Proof of the Kurlberg-Rudnick rate conjecture

By Shamgar Gurevich and Ronny Hadani

To our teacher Joseph Bernstein on the occasion of his 60th birthday

Abstract

In this paper we present a proof of the Hecke quantum unique ergodicity rate conjecture for the Hannay-Berry model of quantum mechanics on the two-dimensional torus. This conjecture was stated in Z. Rudnick’s lectures at MSRI, Berkeley 1999, and ECM, Barcelona 2000.

0. Introduction

0.1. The Hannay-Berry model. In the paper “Quantization of linear maps on the torus-Fresnel diffraction by a periodic grating”, published in 1980 [17], the physicists J. Hannay and Sir M. V. Berry explore a model for quantum mechanics on the two-dimensional symplectic torus $(T,\omega)$. Hannay and Berry suggested quantizing simultaneously the functions on the torus and the linear symplectic group $\Gamma = SL_2(\mathbb{Z})$.

0.2. Quantum chaos. One of their main motivations was to study the phenomenon of quantum chaos [3], [4], [33], [34] in this model. More precisely, they considered an ergodic discrete dynamical system on the torus, which is generated by a hyperbolic automorphism $A \in SL_2(\mathbb{Z})$. Quantizing the system, we replace: the classical phase space $(T,\omega)$ by a finite-dimensional Hilbert space $\mathcal{H}_h$, classical observables, i.e., functions $f \in C^\infty(T)$, by operators $\pi_h(f) \in \text{End}(\mathcal{H}_h)$, and classical symmetries by a unitary representation $\rho_h : SL_2(\mathbb{Z}) \rightarrow U(\mathcal{H}_h)$. A fundamental meta-question in the area of quantum chaos is to understand the ergodic properties of the quantum system $\rho_h(A)$, at least in the semi-classical limit as $h \rightarrow 0$.

0.3. Schnirelman’s theorem. Analogous with the case of the Schrödinger equation, consider the following eigenstate problem:

\[ \rho_h(A)\varphi = \lambda \varphi, \quad \varphi \in \mathcal{H}_h. \]

A fundamental result, valid for a wide class of quantum systems which are associated to ergodic classical dynamics, is Schnirelman’s theorem [35], asserting
that in the semi-classical limit “almost all” eigenstates becomes equidistributed in an appropriate sense. A variant of Schnirelman’s theorem also holds in our situation \[5\]. More precisely, in the semi-classical limit \( \hbar \to 0 \), for “almost all” eigenstates \( \varphi \) of the operator \( \rho_h(A) \), the corresponding Wigner distribution \( \langle \varphi | \pi_{\hbar} (\cdot) | \varphi \rangle : C^\infty (T) \to \mathbb{C} \) approaches the phase space average \( \int_T f \cdot | \omega | \). In this respect, it seems natural to ask whether there exist exceptional sequences of eigenstates? Namely, eigenstates that do not obey the Schnirelman’s rule (“scarred” eigenstates). It was predicted by Berry \[3\], \[4\], that the “scarring” phenomenon is not expected to be seen for quantum systems associated with “generic” chaotic classical dynamics. However, in our situation the dynamical system is not generic, and exceptional eigenstates were constructed. Indeed, it was confirmed mathematically in \[11\], that certain \( \rho_h(A) \)-eigenstates might localize. For example, in that paper, a sequence of eigenstates \( \varphi \) was constructed, for which the corresponding Wigner distribution approaches the measure \( \frac{1}{2} \delta_0 + \frac{1}{2} | \omega | \) on \( T \).

0.4. Hecke quantum unique ergodicity. A quantum system that obeys Schnirelman’s rule is also called quantum ergodic. Can one impose some natural conditions on the eigenstates (0.3.1) so that no exceptional eigenstates will appear? Namely, Quantum Unique Ergodicity will hold. This question was addressed in a paper by Kurlberg and Rudnick \[25\]. In this paper they formulated a rigorous notion of Hecke quantum unique ergodicity for the case \( \hbar = \frac{1}{p} \). The following is a brief description of that work. The basic observation is that the degeneracies of the operator \( \rho_h(A) \) are coupled with the existence of symmetries. There exists a commutative group of operators that commutes with \( \rho_h(A) \). In more detail, the representation \( \rho_h \) factors through the quotient group \( \Gamma_p \cong \text{SL}_2 (\mathbb{F}_p) \). We denote by \( T_A \subset \Gamma_p \) the centralizer of the element \( A \), now considered as an element of the quotient group \( \Gamma_p \). The group \( T_A \) is called (cf. \[25\]) the Hecke torus corresponding to the element \( A \). The Hecke torus acts semisimply on \( H_\hbar \). Therefore, we have a decomposition

\[
H_\hbar = \bigoplus_{\chi : T_A \to \mathbb{C}^*} H_\chi,
\]

where \( H_\chi \) is the Hecke eigenspace corresponding to the character \( \chi \). Consider a unit eigenstate \( \varphi \in H_\chi \) and the corresponding Wigner distribution \( W_\chi : C^\infty (T) \to \mathbb{C} \), defined by the formula \( W_\chi (f) = \langle \varphi | \pi_{\hbar} (f) | \varphi \rangle \). The main statement in \[25\] proves an explicit bound of the semi-classical asymptotic of \( W_\chi (f) \)

\[
\left| W_\chi (f) - \int_T f | \omega | \right| \leq \frac{C_f}{p^{3/4}},
\]
where \( C_f \) is a constant that depends only on the function \( f \). In Rudnick’s lectures at MSRI, Berkeley 1999 [32], and ECM, Barcelona 2000 [33], he conjectured that a stronger bound should hold true; that is,

**Conjecture 0.1 (Rate Conjecture).** The following bound holds:

\[
\left| W_\chi(f) - \int_T f|\omega| \right| \leq \frac{C_f}{p^{1/2}}.
\]

The basic clues suggesting the validity of this stronger bound come from two main sources. The first source is computer simulations [24] accomplished over the years to give extremely precise bounds for considerably large values of \( p \). A more mathematical argument is based on the fact that for special values of \( p \), in which the Hecke torus splits, namely, \( T_A \simeq \mathbb{F}_p^* \), one is able to compute explicitly the eigenstate \( \varphi \in \mathcal{H}_\chi \) and as a consequence to give an explicit formula for the Wigner distribution [26], [6]. More precisely, in case \( \xi \in \mathbb{T}^e \), i.e., a character, the distribution \( W_\chi(\xi) \) turns out to be equal to the exponential sum

\[
\frac{1}{p} \sum_{a \in \mathbb{F}_p^*} \psi\left(\frac{a+1}{a-1}\right) \sigma(a)\chi(a),
\]

where \( \sigma \) denotes the Legendre character, and \( \psi \) is a nontrivial additive character of \( \mathbb{F}_p^* \). This sum is very similar to the Kloosterman sum and the classical Weil bound [36] yields the result.

In this paper a proof for the rate conjecture is presented, treating both cases of split and inert (nonsplit) tori in a uniform manner. A fundamental idea in our approach concerns a nontrivial relation between two seemingly different dynamical systems. One which is attached to a split (“noncompact”) torus and the other which is attached to a nonsplit (“compact”) torus. This relation is geometric in nature and can be formally described in the framework of algebraic geometry.

**0.5. The geometric approach.** The basic observation to be made is that the theory of quantum mechanics on the torus, in case \( \hbar = \frac{1}{p} \), can be equivalently recast in the language of representation theory of finite groups in characteristic \( p \). We will endeavor to give a more precise explanation of this matter. Consider the quotient \( \mathbb{F}_p \)-vector space \( V = \mathbb{T}^e / p\mathbb{T}^e \), where \( \mathbb{T}^e \) is the lattice of characters on \( \mathbb{T} \). We denote by \( H = H(V) \) the Heisenberg group. The group \( \Gamma_p = \text{SL}_2(\mathbb{F}_p) \) is naturally identified with the group of linear symplectomorphisms of \( V \). We have an action of \( \text{SL}_2(\mathbb{F}_p) \) on \( H \). The Stone-von Neumann theorem states that there exists a unique irreducible representation \( \pi : H \rightarrow \text{GL}(\mathcal{H}) \), with the nontrivial central character \( \psi \), for which its isomorphism class is fixed by \( \text{SL}_2(\mathbb{F}_p) \). This is equivalent to saying that \( \mathcal{H} \) is equipped with a compatible projective representation \( \rho : \text{SL}_2(\mathbb{F}_p) \rightarrow \text{PGL}(\mathcal{H}) \). Noting
that $H$ and $\text{SL}_2(\mathbb{F}_p)$ are the sets of rational points of corresponding algebraic
groups, it is natural to ask whether there exist an algebro-geometric object
that underlies the pair $(\pi, \rho)$. The answer to this question is positive. The
construction is proposed in an unpublished letter of Deligne to Kazhdan [10].
Briefly, the content of this letter is a construction of Representation Sheaves
$K_\pi$ and $K_\rho$ on the algebraic varieties $H$ and $\text{SL}_2$ respectively. One obtains, as
a consequence, the following general principle:

\textbf{(*) Motivic Principle.} All quantum mechanical quantities in the Hannay-
Berry model are motivic in nature.

By this we mean that every quantum-mechanical quantity $Q$, is associated
with a vector space $V_Q$ endowed with a Frobenius action $\text{Fr} : V_Q \rightarrow V_Q$, so that

$$Q = \text{Tr}(\text{Fr}_{|V_Q}).$$

The main contribution of this paper is to implement this principle. In partic-
ular, we show that there exists a two-dimensional vector space $V_\chi$, endowed
with an action $\text{Fr} : V_\chi \rightarrow V_\chi$, so that

$$W_\chi(\xi) = \text{Tr}(\text{Fr}_{|V_\chi}).$$

This, combined with a bound on the modulus of the eigenvalues of Frobenius,
i.e.,

$$|\text{e.v}(\text{Fr}_{|V_\chi})| \leq \frac{1}{p^{1/2}},$$

completes the proof of the rate conjecture.

0.6. Remarks. There are several remarks that we would like to make at
this point

Remark 1: Discreteness principle. “Every” quantity $Q$ that appears in the
Hannay-Berry model admits a discrete spectrum in the following arithmetic
sense: $Q$ can take only values which are finite linear combinations of terms with
absolute value of the form $p^{i/2}$ for $i \in \mathbb{Z}$. This is a consequence of the motivic
principle (*) and Deligne’s weight theory [9]. This puts some restrictions on
the possible values of the modulus $|Q|$. We believe that this principle can
be effectively used in various situations in order to derive strong bounds out
of weaker bounds. A striking example would be a possible alternative trivial
“proof” for the bound $|W_\chi(\xi)| \leq \frac{C_\xi}{p^{1/2}}$:

$$|W_\chi(\xi)| \leq \frac{C_\xi}{p^{1/4}} \Rightarrow |W_\chi(\xi)| \leq \frac{C_\xi}{p^{1/2}}.$$

Kurlberg and Rudnick proved in their paper [25] the weaker bound $|W_\chi(\xi)| \leq
\frac{C_\xi}{p^{1/4}}$. This strongly indicates that the stronger bound $|W_\chi(\xi)| \leq \frac{C_\xi}{p^{1/2}}$ is valid.
Remark 2: Higher dimensional exponential sums. The bound that we prove, 
\[ |W_\chi(\xi)| \leq \frac{2+o(1)}{\sqrt{p}}, \] 
for \( \xi \neq 0 \), implies the bound on the operator norm 
\[ \|\mathbf{A}v_{T_A}(\xi)\| \leq \frac{2+o(1)}{\sqrt{p}}, \] 
where \( \mathbf{A}v_{T_A}(\xi) = \frac{1}{|T_A|} \sum_{B \in T_A} \rho_\pi(B) \pi_\pi(\xi) \rho_\pi(B^{-1}) \). This, on the one hand, implies
\begin{align*}
(0.6.1) \quad |\mathbf{A}v_{T_A}(\xi)|_N &\leq \frac{p^{1/N}(2 + o(1))}{\sqrt{p}}, \\
\end{align*}
where \( |\mathbf{A}v_{T_A}(\xi)|_N = (\text{Tr} |\mathbf{A}v_{T_A}(\xi)|^N)^{1/N} \) is the \( N \)-Schatten norm of \( \mathbf{A}v_{T_A}(\xi) \).

On the other hand, one can compute explicitly
\begin{align*}
(0.6.2) \quad |\mathbf{A}v_{T_A}(\xi)|_{2N}^{2N} &= \frac{p}{|T_A|^{2N}} \sum_{(x_1, \ldots, x_{2N}) \in X} \psi \left( \sum_{i<j} \omega(x_i, x_j) \right), \\
\end{align*}
where
\[ X = \{(x_1, \ldots, x_{2N}) | x_i \in \mathcal{O}_\xi, \sum x_i = 0 \} \] and \( \mathcal{O}_\xi = T_A \cdot \xi \subset V \) denotes the orbit of \( \xi \) under the action of \( T_A \). Combining (0.6.1) and (0.6.2) we obtain a nontrivial bound for \( N \geq 3 \) on the higher dimensional exponential sum
\begin{align*}
(0.6.3) \quad \sum_{(x_1, \ldots, x_{2N}) \in X} \psi \left( \sum_{i<j} \omega(x_i, x_j) \right) &\leq \left( \frac{|T_A| \cdot (2 + o(1))}{\sqrt{p}} \right)^{2N} = O(p^N). \\
\end{align*}

It would be interesting to know whether there exists an independent proof for this bound and whether this representation theoretic approach can be used to prove nontrivial bounds for other interesting higher dimensional exponential sums.

0.7. Sato-Tate conjecture. The next level of the theory is to understand the complete statistics of the Hecke-Wigner distributions for different Hecke states. More precisely, let us fix a nonzero character \( \xi \in \mathbb{T}^e. \) For every nonquadratic character \( \chi : T_A \rightarrow \mathbb{C}^* \) we consider the normalized value \( \tilde{W}_\chi(\xi) = \frac{|T_A|}{\sqrt{p}} W_\chi(\xi) \), which lies in the interval \([-2, 2]\) (see Theorem 4.2). Now, running over all multiplicative characters we define the following atomic measure on the interval \([-2, 2]\):
\[ \mu_p = \frac{1}{|T_A|} \sum_{\chi} \delta_{\tilde{W}_\chi(\xi)}. \]
One would like to describe the limit measure (if it exists!). This is the content of another conjecture of Kurlberg and Rudnick [26]:

For an operator \( O \) on a Hilbert space \( \mathcal{H} \), \( |O| = (O^*O)^{1/2} \); for a finite-dimensional space \( |O|_N \leq (\dim \mathcal{H})^{1/2} ||O|| \).
Conjecture (analogue of the Sato-Tate conjecture). The following limit exists:

$$\lim_{p \to \infty} \mu_p = \mu_{ST},$$

where $\mu_{ST}$ is the push-forward of the normalized Haar measure on $SU(2)$ to the interval $[-2, 2]$ through the map $g \mapsto \text{Tr}(g)$.

We hope that using the methodology described in this paper one will be able to gain some progress in proving this conjecture.

Remark. Note that the family $\{\tilde{W}_\chi(\xi)\}_{\chi \in T_A}$ runs over a nonalgebraic space of parameters. Hence, we do not know how to apply Deligne’s equidistribution theory (cf. Weil II [9]) directly in order to solve the Sato-Tate Conjecture.

0.8. Results.

0.8.1. Kurlberg-Rudnick conjecture. The main result of this paper is Theorem 3.1, which is the proof of the Kurlberg-Rudnick rate conjecture (Conjecture 0.1) on the asymptotic behavior of the Hecke-Wigner distributions.

0.8.2. Weil representation. We introduce two new constructions of the Weil representation over finite fields.

(a) The first construction is stated in Theorem 2.3 and is based on the Rieffel quantum torus $A_h$, for $h = \frac{1}{p}$. This approach is essentially equivalent to the classical approach [13], [18], [23], [37] that uses the representation theory of the Heisenberg group in characteristic $p$. The fundamental difference is that the quantum torus is well defined for every value of the parameter $h$.

(b) Canonical Hilbert space (Kazhdan’s question). The second construction uses the “method of Canonical Hilbert Space” (see Appendix A). This approach is based on the following statement:

Proposition (Canonical Hilbert space). Let $(V, \omega)$ be a two-dimensional symplectic vector space over the finite field $\mathbb{F}_q$. There exists a canonical Hilbert space $\mathcal{H}_V$ attached to $(V, \omega)$.

An immediate consequence of this proposition is that all symmetries of $(V, \omega)$ automatically act on $\mathcal{H}_V$. In particular, we obtain a linear representation of the group $Sp = Sp(V, \omega)$ on $\mathcal{H}_V$. This approach has higher dimensional generalization, for the case where $V$ is of dimension $2n$. This generalization will be published by the authors elsewhere.

Remark. Note the main difference of our construction from the classical approach due to Weil (cf. [37]). The classical construction proceeds in two stages. Firstly, one obtains a projective representation of $Sp$, and secondly,
using general arguments about the group Sp one proves the existence of a linearization. A consequence of our approach is that there exists a distinguished linear representation, and its existence is not related to any group theoretic property of Sp. We would like to mention that this approach answers, in the case of the two-dimensional Heisenberg group, a question of Kazhdan [21] dealing with the existence of Canonical Hilbert Spaces for co-adjoint orbits of general unipotent groups. The main motive behind our construction is the notion of oriented Lagrangian subspace. This idea was suggested to us by Bernstein [2].

0.8.3. Deligne’s Weil representation sheaf. We include for the sake of completeness (see Appendix A.4) a formal presentation of Deligne’s letter to Kazhdan [10] that places the Weil representation on a complete algebro-geometric ground. As far as we know, the content of this letter was never published. This construction plays a central role in the proof of the Kurlberg-Rudnick conjecture.

0.9. Structure of the paper. The paper is naturally separated into four parts:

Part I consists of Sections 1, 2 and 3. In Section 1 we discuss classical mechanics on the torus. In Section 2 we discuss quantum mechanics à la Hannay and Berry, using the Rieffel quantum torus model. In Section 3 we formulate the quantum unique ergodicity theorem, i.e., Theorem 3.1. This part of the paper is self-contained and consists of mainly linear algebraic considerations.

Part II: Section 4. This is the main part of the paper, consisting of the proof of the Kurlberg-Rudnick conjecture. The proof is given in two stages. The first stage consists of mainly linear algebraic manipulations to obtain a more transparent formulation of the statement, resulting in Theorem 4.2. In the second stage we venture into algebraic geometry. All linear algebraic constructions are replaced by sheaf theoretic objects, concluding with the Geometrization Theorem, i.e., Theorem 4.4. Next, the statement of Theorem 4.2 is reduced to a geometric statement, the Vanishing Lemma, i.e., Lemma 4.6. The remainder of the section is devoted to the proof of Lemma 4.6. For the convenience of the reader we include a large body of intuitive explanations for all the constructions involved. In particular, we devote some space explaining Grothendieck’s Sheaf-to-Function Correspondence procedure which is the basic bridge connecting Parts I and II.

Part III: Appendix A. In Section A.1 we describe the method of canonical Hilbert space. In Section A.2 we describe the Weil representation in this manifestation. In Section A.3 we relate the invariant construction to the more classical constructions, supplying explicit formulas that will be used later. In
Section A.4 we give a formal presentation of Deligne’s letter to Kazhdan [10].
The main statement of this section is Theorem A.5, in which the Weil representation sheaf $\mathcal{K}$ is introduced. We include in our presentation only the parts of that letter which are most relevant to our needs. In particular, we consider only the two-dimensional case of this letter. In Section A.5 we supply proofs for all technical lemmas and propositions appearing in the previous sections of the appendix.

Part IV: Appendix B. In this appendix we supply the proofs for all statements appearing in Parts I and II. In particular, we give the proof of Theorem 4.4 which essentially consists of taking the Trace of Deligne’s Weil representation sheaf $\mathcal{K}$.

Acknowledgments. It is a pleasure to thank our Ph.D. adviser J. Bernstein for his interest and guidance in this project. We appreciate the contribution of P. Kurlberg and Z. Rudnick who discussed with us their papers and explained their results. We thank P. Sarnak for his invitation to visit the Courant Institute in September 2004 to discuss our work. We would like to thank D. Kazhdan for sharing his thoughts about the possible existence of canonical Hilbert spaces. We thank our friend D. Gaitsgory for the discussions on $\ell$-adic cohomologies and Deligne’s letter. We thank Y. Flicker for helpful remarks. We thank B. Lewis for the editorial work. We thank M. Baruch, the Technion, and M. Teicher, the Emmy Noether institute, for all the support. We would like to acknowledge the referee for very important remarks. Finally, we would like to thank P. Deligne for allowing us to publish his ideas about the geometrization of the Weil representation. S.G. was partially supported by BSF grant #2004200.

1. The classical torus

Let $(\mathbb{T}, \omega)$ be the two-dimensional symplectic torus. Together with its linear symplectomorphisms $\Gamma \simeq \text{SL}_2(\mathbb{Z})$ it serves as a simple model of classical mechanics (a compact version of the phase space of the harmonic oscillator). More precisely, let $\mathbb{T} = W/\Lambda$ where $W$ is a two-dimensional real vector space, i.e., $W \simeq \mathbb{R}^2$ and $\Lambda$ is a rank two lattice in $W$, i.e., $\Lambda \simeq \mathbb{Z}^2$. We obtain the symplectic form on $\mathbb{T}$ by taking a nondegenerate symplectic form on $W$:

$$\omega : W \times W \longrightarrow \mathbb{R}.$$ 

We require $\omega$ to be integral, namely, $\omega : \Lambda \times \Lambda \longrightarrow \mathbb{Z}$ and normalized, i.e., $\text{Vol}(\mathbb{T}) = 1$.

Let $\text{Sp}(W, \omega)$ be the group of linear symplectomorphisms, i.e., $\text{Sp}(W, \omega) \simeq \text{SL}_2(\mathbb{R})$. Consider the subgroup $\Gamma \subset \text{Sp}(W, \omega)$ of elements that preserve the
lattice $\Lambda$, i.e., $\Gamma(\Lambda) \subseteq \Lambda$. Then $\Gamma \simeq \text{SL}_2(\mathbb{Z})$. The subgroup $\Gamma$ is the group of linear symplectomorphisms of $\mathbb{T}$.

We denote by $\Lambda^* \subseteq W^*$ the dual lattice $\Lambda^* = \{\xi \in W^* | \xi(\Lambda) \subset \mathbb{Z}\}$. The lattice $\Lambda^*$ is identified with the lattice of characters of $\mathbb{T}$ by the following map:

$$\xi \in \Lambda^* \mapsto e^{2\pi i <\xi, \cdot>} \in \mathbb{T}^e,$$

where $\mathbb{T}^e = \text{Hom}(\mathbb{T}, \mathbb{C}^*)$.

1.1. The classical mechanical system. We consider a very simple discrete mechanical system. A hyperbolic element $A \in \Gamma$, i.e., $|\text{Tr}(A)| > 2$, generates an ergodic discrete dynamical system. The Birkhoff Ergodic Theorem states that

$$\lim_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} f(A^k x) = \int_{\mathbb{T}} f|\omega|,$$

for every $f \in \mathcal{S}(\mathbb{T})$ and for almost every point $x \in \mathbb{T}$. Here $\mathcal{S}(\mathbb{T})$ stands for a good class of functions, for example, trigonometric polynomials or smooth functions.

We fix a hyperbolic element $A \in \Gamma$ for the remainder of the paper.

2. Quantization of the torus

Quantization is one of the big mysteries of modern mathematics; indeed it is not at all clear what the precise structure is which underlies quantization in general. Although physicists have been using quantization for almost a century, for mathematicians the concept remains altogether unclear. Yet, in specific cases, there are certain formal models for quantization that are well justified mathematically. The case of the symplectic torus is one of these cases. Before we employ the formal model, it is worthwhile to discuss the general phenomenological principles of quantization which are surely common for all models.

Let us start with a model of classical mechanics, namely, a symplectic manifold, serving as a classical phase space. In our case this manifold is the symplectic torus $\mathbb{T}$. Principally, quantization is a protocol by which one associates a quantum “phase” space $\mathcal{H}$ to the classical phase space $\mathbb{T}$, where $\mathcal{H}$ is a Hilbert space. In addition, the protocol gives a rule by which one associates to every classical observable, namely a function $f \in \mathcal{S}(\mathbb{T})$, a quantum observable $\text{Op}(f) : \mathcal{H} \to \mathcal{H}$, an operator on the Hilbert space. This rule should send a real function into a self-adjoint operator.

To be more precise, quantization should be considered not as a single protocol, but as a one-parameter family of protocols, parametrized by $\hbar$, the Planck constant. For every fixed value of the parameter $\hbar$ there is a protocol which associates to $\mathbb{T}$ a Hilbert space $\mathcal{H}_\hbar$ and for every function $f \in \mathcal{S}(\mathbb{T})$ an
operator $\text{Op}_h(f) : \mathcal{H}_h \to \mathcal{H}_h$. Again the association rule should send real functions to self-adjoint operators.

Accepting the general principles of quantization, one searches for a formal model by which to quantize, that is, a mathematical model which will manufacture a family of Hilbert spaces $\mathcal{H}_h$ and association rules $\mathcal{S}(\mathbb{T}) \leadsto \text{End}(\mathcal{H}_h)$. In this work we employ a model of quantization called the \textit{Weyl quantization model}.

2.1. \textit{The Weyl quantization model}. The Weyl quantization model works as follows. Let $\mathcal{A}_h$ be a one-parameter deformation of the algebra $\mathcal{A}$ of trigonometric polynomials on the torus. This algebra is known in the literature as the Rieffel torus [31]. The algebra $\mathcal{A}_h$ is constructed by taking the free unital associative algebra over $\mathbb{C}$ generated by the symbols $\{s(\xi) \mid \xi \in \Lambda^*\}$ and quotienting out by the relations $s(\xi)s(\eta) = e^{\pi i \hbar \omega(\xi,\eta)}s(\xi + \eta)$ and $s(0) = 1$. Here $\omega$ is the form on $W^*$ induced by the original form $\omega$ on $W$. We point out two facts about the algebra $\mathcal{A}_h$. First, when substituting $\hbar = 0$ one gets the group algebra of $\Lambda^*$, which is exactly equal to the algebra of trigonometric polynomials on the torus. Second, the algebra $\mathcal{A}_h$ contains as a standard basis the lattice $\Lambda^*$:

$$s : \Lambda^* \to \mathcal{A}_h.$$ 

Therefore, one can identify the algebras $\mathcal{A}_h \simeq \mathcal{A}$ as vector spaces, where every function $f \in \mathcal{A}$ can be viewed as an element of $\mathcal{A}_h$.

For a fixed $\hbar$, a representation $\pi_\hbar : \mathcal{A}_h \to \text{End}(\mathcal{H}_h)$ serves as a quantization protocol; that is, for every function $f \in \mathcal{A}$ one has

$$f \in \mathcal{A} \simeq \mathcal{A}_h \to \pi_\hbar(f) \in \text{End}(\mathcal{H}_h).$$

An equivalent way of saying this is

$$f \mapsto \sum_{\xi \in \Lambda^*} a_\xi \pi_\hbar(\xi),$$

where $f = \sum_{\xi \in \Lambda^*} a_\xi \cdot \xi$ is the Fourier expansion of $f$.

To summarize: every family of representations $\pi_\hbar : \mathcal{A}_h \to \text{End}(\mathcal{H}_h)$ gives us a complete quantization protocol. Yet, a serious question now arises, namely what representations to choose? Is there a correct choice of representations, both mathematically, but also perhaps physically? A possible restriction on the choice is to choose an irreducible representation. Nevertheless, some ambiguity still remains because there are several irreducible classes for specific values of $\hbar$.

We present here a partial solution to this problem in the case where the parameter $\hbar$ is restricted to take only rational values [15]. Even more particularly, we take $\hbar$ to be of the form $\hbar = \frac{1}{p}$ where $p$ is an odd prime number. Before any formal discussion one should recall that our classical object is the symplectic torus $\mathbb{T}$ \textit{together} with its linear symplectomorphisms $\Gamma$. We would
like to quantize not only the observables $\mathcal{A}$, but also the symmetries $\Gamma$. Next, we shall construct an equivariant quantization of $\mathbb{T}$.

2.2. Equivariant Weyl quantization of the torus. Let $h = \frac{1}{p}$ and consider the additive character $\psi : \mathbb{F}_p \rightarrow \mathbb{C}^*$, $\psi(t) = e^{\frac{2\pi it}{p}}$. We give here a slightly different presentation of the algebra $\mathcal{A}_h$. Let $\mathcal{A}_h$ be the unital associative $\mathbb{C}$-algebra generated by the symbols $\{ s(\xi) \mid \xi \in \Lambda^* \}$ and the relations $s(\xi)s(\eta) = \psi(\frac{1}{2} \omega(\xi, \eta))s(\xi + \eta)$, $s(0) = 1$. Here we consider $\omega$ as a map $\omega : \Lambda^* \times \Lambda^* \rightarrow \mathbb{F}_p$. The lattice $\Lambda^*$ serves as a standard basis for $\mathcal{A}_h$:

$$s : \Lambda^* \rightarrow \mathcal{A}_h.$$ 

The group $\Gamma$ acts on the lattice $\Lambda^*$, therefore, it acts on $\mathcal{A}_h$. It is easy to see that $\Gamma$ acts on $\mathcal{A}_h$ by homomorphisms of algebras. For an element $B \in \Gamma$, we denote by $f \mapsto f^B$ the action of $B$ on an element $f \in \mathcal{A}_h$.

Remark 2.1. This presentation of the algebra $\mathcal{A}_h$ was discovered in [16]. The two defining relations differ by $(-1)^{\omega(\xi, \eta)} = \text{sign}(\xi + \eta)\text{sign}(\xi)\text{sign}(\eta)$, where $\text{sign}(\xi) = 1$ if $\xi \in 2\Lambda^*$, $\text{sign}(\xi) = -1$ if $\xi \notin 2\Lambda^*$. One has a $\Gamma$-equivariant isomorphism from the algebra defined by the first presentation to the algebra defined by the second presentation, sending $s(\xi)$ in the first to $\text{sign}(\xi)s(\xi)$ in the second.

An equivariant quantization of the torus is a pair

$$\pi_h : \mathcal{A}_h \rightarrow \text{End}(\mathcal{H}_h),$$

$$\rho_h : \Gamma \rightarrow \text{PGL}(\mathcal{H}_h),$$

where $\pi_h$ is a representation of $\mathcal{A}_h$ and $\rho_h$ is a projective representation of $\Gamma$. These two should be compatible in the following manner:

$$\rho_h(B)\pi_h(f)\rho_h(B)^{-1} = \pi_h(f^B),$$

for every $B \in \Gamma$ and $f \in \mathcal{A}_h$. Equation (2.2.1) is called the Egorov identity.

Let us suggest now a construction of an equivariant quantization of the torus. Given a representation $\pi : \mathcal{A}_h \rightarrow \text{End}(\mathcal{H})$ and an element $B \in \Gamma$, we construct a new representation $\pi^B : \mathcal{A}_h \rightarrow \text{End}(\mathcal{H})$:

$$\pi^B(f) = \pi(f^B).$$

This gives an action of $\Gamma$ on the set $\text{Irr}(\mathcal{A}_h)$ of classes of irreducible representations. The set $\text{Irr}(\mathcal{A}_h)$ has a very regular structure as a principal homogeneous space over $\mathbb{T}$. Moreover, every irreducible representation of $\mathcal{A}_h$ is finite dimensional and of dimension $p$. The following theorem plays a central role in the construction.
Theorem 2.2 (Canonical invariant representation [15]). Let $\hbar = \frac{1}{p}$, where $p$ is a prime. There exists a unique (up to isomorphism) irreducible representation $(\pi_\hbar, \mathcal{H}_\hbar)$ of $A_\hbar$ for which its equivalence class is fixed by $\Gamma$.

Let $(\pi_\hbar, \mathcal{H}_\hbar)$ be a representative of the fixed irreducible equivalence class. Then for every $B \in \Gamma$ we have

$$\pi^B_\hbar \simeq \pi_\hbar.$$  

This means that for every element $B \in \Gamma$ there exists an operator $\rho_\hbar(B)$ acting on $\mathcal{H}_\hbar$ which realizes the isomorphism (2.2.3). The collection $\{\rho_\hbar(B) : B \in \Gamma\}$ constitutes a projective representation

$$\rho_\hbar : \Gamma \rightarrow \text{PGL}(\mathcal{H}_\hbar).$$

Equations (2.2.2) and (2.2.3) also imply the Egorov identity (2.2.1).

The group $\Gamma \simeq \text{SL}_2(\mathbb{Z})$ is almost a free group and it is finitely presented. A brief analysis [15] shows that every projective representation of $\Gamma$ can be lifted (linearized) into a true representation. More precisely, it can be linearized in 12 different ways, where 12 is the number of characters of $\Gamma$. In particular, the projective representation (2.2.4) can be linearized (not uniquely) into an honest representation. The next theorem (to be proved in Appendix B) proposes the existence of a canonical linearization. Let $\Gamma_p \simeq \text{SL}_2(\mathbb{F}_p)$ denote the quotient group of $\Gamma$ modulo $p$.

Theorem 2.3 (Canonical linearization). Let $\hbar = \frac{1}{p}$, where $p \neq 2, 3$. There exists a unique linearization $\rho_\hbar : \Gamma \rightarrow \text{GL}(\mathcal{H}_\hbar)$, characterized by the property that it factors through the quotient group $\Gamma_p

$$\begin{align*}
\Gamma & \quad \xrightarrow{\rho_\hbar} \quad \Gamma_p \\
& \downarrow \quad \downarrow \\
\rho_\hbar & \quad \rightarrow \quad \text{GL}(\mathcal{H}_\hbar).
\end{align*}$$

From now on $\rho_\hbar$ means the linearization of Theorem 2.3.

Summary. Theorem 2.2 confirms the existence of a unique invariant representation of $A_\hbar$, for every $\hbar = \frac{1}{p}$. This gives a canonical equivariant quantization $(\pi_\hbar, \rho_\hbar, \mathcal{H}_\hbar)$. Moreover, for $p \neq 2, 3$ by Theorem 2.3, the projective

---

2Theorem 2.2 holds more generally, i.e., for all Planck constants of the form $\hbar = M/N$ where $M, N$ are co-prime integers. However, in this paper we will not need to consider this generality.
representation \( \rho_h \) can be linearized in a canonical way to give an honest representation of \( \Gamma \) which factors through \( \Gamma_p \).\(^3\) Altogether, this gives a pair
\[
\pi_h : \mathcal{A}_h \rightarrow \text{End}(\mathcal{H}_h), \\
\rho_h : \Gamma_p \rightarrow \text{GL}(\mathcal{H}_h)
\]
satisfying the following compatibility condition (Egorov identity)
\[
\rho_h(B)\pi_h(f)\rho_h(B)^{-1} = \pi_h(fB),
\]
for every \( B \in \Gamma_p, f \in \mathcal{A}_h \). The notation \( \pi_h(fB) \) means that we take any pre-image \( \tilde{B} \in \Gamma \) of \( B \in \Gamma_p \) and act by it on \( f \). Note, that the operator \( \pi_h(fB) \) does not depend on the choice of \( \tilde{B} \). In the following, we denote the Weil representation \( \tilde{\rho}_h \) by \( \rho_h \) and consider \( \Gamma_p \) to be the default domain.

2.3. The quantum mechanical system. Let \( (\pi_h, \rho_h, \mathcal{H}_h) \) be the canonical equivariant quantization. Let \( A \) be our fixed hyperbolic element, considered as an element of \( \Gamma_p \). The element \( A \) generates a quantum dynamical system as follows. Take a (pure) quantum state \( \varphi \in S(\mathcal{H}_h) = \{ \varphi \in \mathcal{H}_h : \|\varphi\| = 1 \} \) and act on it with \( A \)
\[
\varphi \mapsto \varphi^A = \rho_h(A)\varphi. \tag{2.3.1}
\]

3. Hecke Quantum Unique Ergodicity

The main silent question of this paper is whether the system \( (2.3.1) \) is quantum ergodic. Before discussing this question, one is obliged to define a notion of quantum ergodicity. As a first approximation, follow the classical definition, but replace each classical notion by its quantum counterpart. That is, for every \( f \in \mathcal{A}_h \) and almost every quantum state \( \varphi \in S(\mathcal{H}_h) \), the following holds:
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \langle \varphi | \pi_h(f^{A^k}) \varphi \rangle = \int_{\mathbb{T}} f |\omega|, \tag{3.0.2}
\]
Unfortunately (3.0.2) is literally not true. The limit is never exactly equal to the integral for a fixed \( h \). Let us now give a true statement which is a slight modification of (3.0.2), called the Hecke Quantum Unique Ergodicity. First, rewrite (3.0.2) in an equivalent form. Now,
\[
\langle \varphi | \pi_h(f^{A^k}) \varphi \rangle = \langle \varphi | \rho_h(A^k)\pi_h(f)\rho_h(A^k)^{-1} \varphi \rangle, \tag{3.0.3}
\]
when we use the Egorov identity \( (2.2.1) \).

---

\(^3\)This is the famous Weil representation of \( \text{SL}_2(\mathbb{F}_p) \).
Next, note that the elements $A^k$ run inside the finite group $\Gamma_p$. Denote by $\langle A \rangle \subseteq \Gamma_p$ the cyclic subgroup generated by $A$. It is easy to see, by (3.0.3), that
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \langle \varphi | \pi_n(f^{A_k}) \varphi \rangle = \frac{1}{|\langle A \rangle|} \sum_{B \in \langle A \rangle} \langle \varphi | \rho_n(B) \pi_n(f) \rho_n(B)^{-1} \varphi \rangle.
\]
Altogether, (3.0.2) can be written in the form
\[
(3.0.4) \quad \text{Av}_{\langle A \rangle} (\langle \varphi | \pi_n(f) \varphi \rangle) = \sqrt{\int_T |f| \omega},
\]
where $\text{Av}_{\langle A \rangle}$ denotes the average of the Wigner distribution $\langle \varphi | \pi_n(f) \varphi \rangle$ with respect to the group $\langle A \rangle$.

3.1. Hecke theory. Denote by $T_A$ the centralizer of $A$ in $\Gamma_p \cong \text{SL}_2(\mathbb{F}_p)$. The finite group $T_A$ consists of the rational points of an algebraic group $T_A$. Moreover, in the case where the characteristic of the field does not divide $\text{Tr}(A)^2 - 4$, the group $T_A$ is an algebraic torus. We call $T_A$ the Hecke torus (cf. [25]). One has, $\langle A \rangle \subseteq T_A \subseteq \Gamma_p$. Now, in (3.0.4) take the average with respect to the group $T_A$ instead of the group $\langle A \rangle$. The statement of the Kurlberg-Rudnick rate conjecture (cf. [25], [32], [33]) is given in the following theorem.

**Theorem 3.1** (Hecke Quantum Unique Ergodicity). Let $h = \frac{1}{p}$, where $p$ is a sufficiently large prime. For every $f \in A_h$ and $\varphi \in S(\mathcal{H}_h)$, we have
\[
(3.1.1) \quad \left| \text{Av}_{T_A} (\langle \varphi | \pi_n(f) \varphi \rangle) - \int_T |f| \omega \right| \leq \frac{C_f}{\sqrt{p}},
\]
where $C_f$ is an explicit constant depending only on $f$.

Section 4 is devoted to proving Theorem 3.1.

4. Proof of the Hecke Quantum Unique Ergodicity Conjecture

The proof is given in two stages. The first stage is a preparation stage and consists mainly of linear algebra considerations. We reduce statement (3.1.1) in several steps into an equivalent statement which will be better suited to our needs. In the second stage, we introduce the main part of the proof, invoking

---

4Our formulation is equivalent to the original statement [25], which treats only the case of common eigenstates of the Hecke torus.

5What one really needs here is that any nontrivial fixed element $\xi \in \Lambda^*$ will not be an eigenvector for the action of $A$ on the quotient $\mathbb{F}_p$-vector space $\Lambda^*/p\Lambda^*$ for sufficiently large $p$. Hence, Theorem 3.1 holds true for every regular element in $\Gamma$ that has no eigenvectors in the integral lattice $\Lambda^*$. The last property holds not only for hyperbolic elements! For example, Theorem 3.1 holds for the Weyl element $w = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$.
tools from algebraic geometry in the framework of ℓ-adic sheaves and ℓ-adic cohomology (cf. [29], [1]).

4.1. Preparation stage. Step 1. It is sufficient to prove Theorem 3.1 for the case when \( f \) is a nontrivial character \( \xi \in \Lambda^* \). Because \( \int_T \xi|\omega| = 0 \), statement (3.1.1) becomes

\[
\left| \mathbf{Av}_{T_A} \left( \langle \varphi | \pi_h(\xi) \varphi \rangle \right) \right| \leq \frac{C_\xi}{\sqrt{p}}.
\]

The statement for general \( f \in \mathcal{A}_h \) follows directly from the triangle inequality.

Step 2. It is enough to prove (4.1.1) in case \( \varphi \in S(\mathcal{H}_h) \) is a Hecke eigenstate. To be more precise, the Hecke torus \( T_A \) acts semisimply on \( \mathcal{H}_h \) via the representation \( \rho_h \), thus \( \mathcal{H}_h \) decomposes to a direct sum of character spaces

\[
\mathcal{H}_h = \bigoplus_{\chi : T_A \rightarrow \mathbb{C}^*} \mathcal{H}_\chi.
\]

The sum in (4.1.2) is over multiplicative characters of the torus \( T_A \). For every \( \varphi \in \mathcal{H}_\chi \) and \( B \in T_A \), we have

\[
\rho_h(B)\varphi = \chi(B)\varphi.
\]

Taking \( \varphi \in \mathcal{H}_\chi \), statement (4.1.1) becomes

\[
|\langle \varphi | \pi_h(\xi) \varphi \rangle| \leq \frac{C_\xi}{\sqrt{p}}.
\]

Here \( C_\xi = 2 + o(1) \), where we use here the standard \( o(1) \) notation.\(^6\)

The averaged operator

\[
\mathbf{Av}_{T_A}(\pi_h(\xi)) = \frac{1}{|T_A|} \sum_{B \in T_A} \rho_h(B)\pi_h(\xi)\rho_h(B)^{-1}
\]

is essentially\(^7\) diagonal in the Hecke base. Knowing this, we see that statement (4.1.1) follows from (4.1.3) by invoking the triangle inequality.

Step 3. Let \( P_\chi : \mathcal{H}_h \rightarrow \mathcal{H}_h \) be the orthogonal projector on the eigenspace \( \mathcal{H}_\chi \).

\(^6\)In the case where \( T_A \) is nonsplit we have \( C_\xi = 2 \).

\(^7\)This follows from Remark 4.1. If \( T_A \) does not split over \( \mathbb{F}_p \), then \( \mathbf{Av}_{T_A}(\pi_h(\xi)) \) is diagonal in the Hecke basis. In case \( T_A \) splits, then for the Legendre character \( \sigma \) we have that \( \dim \mathcal{H}_\sigma = 2 \). However, in the latter case one can prove (4.1.1) for \( \varphi \in \mathcal{H}_\sigma \) by a computation of explicit eigenstates (cf. [26]).
The projector $P_\chi$ can be defined in terms of the representation $\rho_\hbar$:

$$
P_\chi = \frac{1}{|T_A|} \sum_{B \in T_A} \chi^{-1}(B)\rho_\hbar(B).
$$

Now write (4.1.3) in the form

$$(4.1.5) \left| \sum_{B \in T_A} \text{Tr}(\rho_\hbar(B)\pi_\hbar(\xi))\chi(B) \right| \leq \frac{C_\xi}{\sqrt{p}}.$$ 

On noting that $|T_A| = p \pm 1$ and multiplying both sides of (4.1.5) by $|T_A|$, we obtain that it is sufficient to prove the following statement:

**Theorem 4.2** (Hecke Quantum Unique Ergodicity (restated)). *Fix a non-trivial $\xi \in \Lambda^*$. Let $\hbar = \frac{1}{p}$, where $p$ is a sufficiently large prime. For every character $\chi$ the following holds:

$$
\left| \sum_{B \in T_A} \text{Tr}(\rho_\hbar(B)\pi_\hbar(\xi))\chi(B) \right| \leq 2\sqrt{p}.
$$

$4.2$. *The trace function.* We prove Theorem 4.2 using sheaf theoretic techniques. Before diving into geometric considerations, we investigate further the ingredients appearing in Theorem 4.2. Denote by $F$ the function $F : \Gamma_p \times \Lambda^* \rightarrow \mathbb{C}$ defined by

$$(4.2.1) \quad F(B, \xi) = \text{Tr}(\rho_\hbar(B)\pi_\hbar(\xi)).$$

We denote by $V = \Lambda^*/p\Lambda^*$ the quotient vector space, i.e., $V \simeq \mathbb{F}_p^2$. The symplectic form $\omega$ specializes to give a symplectic form on $V$. The group $\Gamma_p$ is the group of linear symplectomorphisms of $V$, i.e., $\Gamma_p = \text{Sp}(V)$. Set $Y_0 = \Gamma_p \times \Lambda^*$ and $Y = \Gamma_p \times V$. One has (for a proof, see §B.2) the quotient map

$$Y_0 \rightarrow Y.$$ 

---

This fact, which is needed if we want to stick with the matrix coefficient formulation of the conjecture, can be proven by algebro-geometric techniques or alternatively by a direct computation (cf. [13]).
Lemma 4.3. The function $F : Y_0 \longrightarrow \mathbb{C}$ factors through the quotient $Y$.

\[ Y_0 \xrightarrow{F} Y \xrightarrow{\mathbb{C}} Y. \]

Denote the function $\overline{F}$ also by $F$ and from now on consider $Y$ as the default domain. The function $F : Y \longrightarrow \mathbb{C}$ is invariant under a certain group action of $\Gamma_p$. To be more precise, let $S \in \Gamma_p$. Then

$$\text{Tr}(\rho_h(B)\pi_h(\xi)) = \text{Tr}(\rho_h(S)\rho_h(B)\rho_h(S)^{-1}\rho_h(S)\pi_h(\xi)\rho_h(S)^{-1}).$$

Applying the Egorov identity (2.2.1) and using the fact that $\rho_h$ is a representation we get

$$\text{Tr}(\rho_h(S)\rho_h(B)\rho_h(S)^{-1}\rho_h(S)\pi_h(\xi)\rho_h(S)^{-1}) = \text{Tr}(\pi_h(S\xi)\rho_h(SBS^{-1})).$$

Finally, we have

$$(4.2.2) \quad F(B, \xi) = F(SBS^{-1}, S\xi).$$

Putting (4.2.2) in a more diagrammatic form, we have an action of $\Gamma_p$ on $Y$ given by the following formula:

$$(4.2.3) \quad \Gamma_p \times Y \xrightarrow{\alpha} Y, \quad (S, (B, \xi)) \longrightarrow (SBS^{-1}, S\xi).$$

Consider the following diagram:

$$Y \xleftarrow{\text{pr}} \Gamma_p \times Y \xrightarrow{\alpha} Y,$$

where $\text{pr}$ is the projection on the $Y$ variable. Formula (4.2.2) can be stated equivalently as

$$\alpha^*(F) = \text{pr}^*(F),$$

where $\alpha^*(F)$ and $\text{pr}^*(F)$ are the pullbacks of the function $F$ on $Y$ via the maps $\alpha$ and $\text{pr}$ respectively.

4.3. Geometrization (sheafification). Our next goal is to reduce Theorem 4.2 to a geometric statement, i.e., Lemma 4.6. The main tool which we invoke is called the “Geometrization” procedure. In this procedure one replaces sets by algebraic varieties and functions by sheaf theoretic objects (which are quite similar to vector bundles). The main statement of this section will be presented in the “Geometrization Theorem”, i.e., Theorem 4.4.

4.3.1. Algebraic geometry. First, we have to devote some space recalling notions and notation from algebraic geometry over finite fields and the theory of $\ell$-adic sheaves.
Varieties. In the sequel, we shall translate back and forth between algebraic varieties defined over the finite field \( \mathbb{F}_p \), and their corresponding sets of rational points. In order to prevent confusion between the two, we use bold-face letters for denoting a variety \( X \), and normal letters for denoting its corresponding set of rational points \( X \). Fix an algebraic closure \( \overline{\mathbb{F}}_p \). For us, a variety \( X \) over the finite field is a quasi projective algebraic variety over \( \mathbb{F}_p \), equipped with a (geometric) Frobenius endomorphism \( \text{Fr} : X \to X \). In more detail, \( X \) can be realized as a (Zariski) open set in a projective variety, defined by homogeneous polynomials with coefficients in the finite field \( \mathbb{F}_p \) and in this realization, \( \text{Fr} \) is given by raising the coordinates to the \( p \)-th power. We denote by \( \mathcal{X} \) the set of points fixed by the Frobenius, \( \mathcal{X} = \mathcal{X}^{\text{Fr}} = \{ x \in X : \text{Fr}(x) = x \} \). Another common notation for this set is \( \mathcal{X} = \mathcal{X}(\mathbb{F}_p) \).

Sheaves. For a prime \( \ell \neq p \) we denote by \( D^b_c(X) = D^b_c(X, \mathbb{Q}_\ell) \) the “derived” category of constructible \( \ell \)-adic sheaves on \( X \) (see [9] for the construction of this category and [1], [29] for reference). A constructible \( \mathbb{Q}_\ell \)-sheaf on \( X \) in the sense of [1], [29] gives an object of \( D^b_c(X) \), and the objects of \( D^b_c(X) \) will also referred to as “sheaves” when no confusion can arise. We denote by \( \text{Perv}(X) \) the Abelian category of perverse sheaves on \( X \), that is, the heart with respect to the autodual perverse \( t \)-structure in \( D^b_c(X) \) (cf. [1]). We will use also the notion of \( N \)-perversity: an object \( F \) in \( D^b_c(X) \) is called \( N \)-perverse if \( F[N] \in \text{Perv}(X) \).

Finally, we define the notion of a Weil structure (or Frobenius structure). By a Weil structure on an object \( F \in D^b_c(X) \) we mean an isomorphism
\[
\theta : \text{Fr}^* F \simeq F.
\]

The pair \( (F, \theta) \) above is called a Weil object. By an abuse of notation we often denote \( \theta \) also by \( \text{Fr} \). We fix an identification \( \overline{\mathbb{Q}}_\ell \simeq \mathbb{C} \). Therefore, all sheaves are considered to be with coefficients the complex numbers.

In the sequel we will use the following two standard sheaves (see Definition 1.7 in [7]). We denote by \( \mathcal{L}_\psi \) the Artin-Schreier sheaf on the group \( \mathbb{G}_a \) that corresponds to the additive character \( \psi \) on the group \( \mathbb{F}_p = \mathbb{G}_a(\mathbb{F}_p) \), and by \( \mathcal{L}_\chi \) the Kummer sheaf on the multiplicative group \( \mathbb{G}_m \) which corresponds to the multiplicative character \( \chi \) on the group \( \mathbb{F}_p^* = \mathbb{G}_m(\mathbb{F}_p) \). A particular important example is the sheaf \( \mathcal{L}_\sigma \) which corresponds to the Legendre quadratic character \( \sigma \).

4.3.2. The Geometrization Theorem. Considering the above, we can begin replacing all our sets with their corresponding algebraic varieties. The symplectic vector space \( (\mathcal{V}, \omega) \) is identified as the set of rational points of an algebraic variety \( \mathcal{V} \). The variety \( \mathcal{V} \) is equipped with a morphism \( \omega : \mathcal{V} \times \mathcal{V} \to \mathbb{F}_p \) respecting the Frobenius structure on both sides. The group \( \Gamma_p \) is identified as
the set of rational points of the algebraic group $\text{Sp}$. Finally, the set $Y$ is identified as the set of rational points of the algebraic variety $Y$. More precisely, $Y \cong \text{Sp} \times V$. We denote by $\alpha$ the action of $\text{Sp}$ on the variety $Y$ (cf. (4.2.3)). We fix once an identification of the symplectic vector space with the standard symplectic plane

\[(4.3.1) \quad (V, \omega) \cong (\mathbb{A}^2, \omega_{\text{std}}),\]

where $\omega_{\text{std}}$ is the standard symplectic form defined by the condition

$$\omega_{\text{std}}((1,0),(0,1)) = 1.$$ 

This induces an identification

\[(4.3.2) \quad \text{Sp} \cong \text{SL}_2.\]

Consider the standard torus $T \subset \text{SL}_2$; i.e., $T$ consists of diagonal matrices of the form $\begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix}$. We use the notation $T^\times$ to denote the punctured torus $T - \{I\}$.

Our next goal is to replace functions by appropriate sheaf-theoretic objects. The following theorem (for a proof, see §B.3) proposes an appropriate sheaf-theoretic object standing in place of the function $F : Y \to \mathbb{C}$ (4.2.1).

**Theorem 4.4 (Geometrization Theorem).** There exists a Weil object $F \in \mathcal{D}^b_c(Y)$ satisfying the following properties:

1. (Perversity) The object $F$ is geometrically irreducible, $\dim(Y)$- perverse of pure weight $w(F) = 0.9$
2. (Function) The function $F$ is associated to $F$ via sheaf-to-function correspondence $f^F = F$.
3. (Equivariance) For every element $S \in \text{Sp}$ there exists an isomorphism $\alpha^*_S F \cong F$.
4. (Formula) Restriction of $F$ to the subvariety $T^\times \times V$. Using the identifications (4.3.1), (4.3.2), we have an explicit formula

\[(4.3.3) \quad F|_{T^\times \times V} \left( \begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix}, \lambda, \mu \right) \cong \mathcal{L}_{\sigma(a)} \otimes \mathcal{L}_{\psi(\frac{1}{2} a^{-1}, \lambda, \mu)}.

**Comments.**

1. In Property 3, in fact, a finer statement is true. In the case that $S \in \text{Sp}(\mathbb{F}_q)$, $q = p^n$, one can show that the isomorphism $\alpha^*_S F \cong F$ is an isomorphism of Weil sheaves on $Y$, considered as an algebraic variety defined over $\mathbb{F}_q$.

---

9We thank the referee for bringing to our attention a deep observation regarding these striking properties.
2. In Property 4, one can produce an invariant formula, without using any identification. Moreover, this formula is valid on an open subvariety. We shall now explain this further. Let $j : \Omega \hookrightarrow \text{Sp}$ denote the open subvariety consisting of elements $g \in \text{Sp}$ such that $g - I$ is invertible. Restricting the sheaf $\mathcal{F}$ to the open subvariety $\Omega \times \mathbf{V}$, we have the following isomorphism:

$$\mathcal{F}|_{\Omega \times \mathbf{V}} \simeq \mathcal{L}(\psi(\frac{1}{4} \omega(\frac{g+I}{g-I}v,v))) \otimes \mathcal{L}_\sigma(\text{Tr}(g)-2).$$  \(^{10}\)

A direct calculation verifies that the invariant formula (4.3.4) coincides with the coordinate dependent formula (4.3.3) when one restricts to the standard (punctured) torus $T^\times$.

**Explanations.** We give here an intuitive explanation of Theorem 4.4, part by part, as it was stated. An object $\mathcal{F} \in D^b_c(Y)$ can be considered as a vector bundle $\mathcal{F}$ over $Y$:

$$\begin{array}{c}
\mathcal{F} \\
\downarrow \\
Y
\end{array}$$

Saying that $\mathcal{F}$ is a *Weil sheaf* means that it is equipped with a lifting of the Frobenius, that is

$$\begin{array}{c}
\mathcal{F} \leftarrow^{\text{Fr}} \\
\downarrow \\
Y
\end{array} \quad \begin{array}{c}
\mathcal{F} \rightarrow^{\text{Fr}} \\
\downarrow \\
Y
\end{array}$$

**Remark.** We deliberately choose the lifting above in the opposite direction in order to make our intuitive explanation consistent with the formal definitions.

To be even more precise, think of $\mathcal{F}$ not as a single vector bundle, but as a complex $\mathcal{F} = \mathcal{F}^\bullet$ of vector bundles over $Y$

$$\begin{array}{c}
\cdots \rightarrow \mathcal{F}^{-1} \rightarrow \mathcal{F}^0 \rightarrow \mathcal{F}^1 \rightarrow \cdots
\end{array}$$

\(^{10}\)In particular, this implies that on the whole space the sheaf $\mathcal{F}$ coincides with the middle extension $(j \times \text{Id}_Y)_!\mathcal{L}(\psi(\frac{1}{4} \omega(\frac{g+I}{g-I}v,v))) \otimes \mathcal{L}_\sigma(\text{Tr}(g)-2))$ for the $t$-structure whose heart is the class of $\text{dim}(Y)$-perverse sheaves. This means that one obtains a complete description of the sheaf $\mathcal{F}$. 
The complex $F^\bullet$ is equipped with a lifting of Frobenius

$$
\cdots \xrightarrow{d} F^{r-1} \xrightarrow{d} F^0 \xrightarrow{d} F^1 \xrightarrow{d} \cdots
$$

Here the Frobenius commutes with the differentials. Next, we explain the meaning of Property 1. We will not try to explain here the notion of perversity, nor the notion of purity, in order not to divert (see the references [1], [9]). It is adequate for the purpose of this paper to explain the meaning of the sheaf $F$ being of a mixed weight $w(F) \leq 0$. This condition is implied by the condition of $F$ being of pure weight $w(F) = 0$. Let $y \in Y$ be a point fixed by the $n$-th power ($n > 0$) of the Frobenius. Denote by $F_y$ the fiber of $F$ at the point $y$. Thinking of $F$ as a complex of vector bundles, we see clearly what is meant taking the fiber at a point. The fiber $F_y$ is just a complex of vector spaces. Because the point $y$ is fixed by $Fr^n$, it induces an endomorphism of $F_y$

$$
\cdots \xrightarrow{d} F^{r-1}_y \xrightarrow{d} F^0_y \xrightarrow{d} F^1_y \xrightarrow{d} \cdots
$$

The endomorphism $Fr^n$ acting as in (4.3.5) commutes with the differentials. Hence, it induces an action on cohomologies. For every $i \in \mathbb{Z}$ we have an endomorphism

$$
Fr^n : H^i(F_y) \longrightarrow H^i(F_y).
$$

To say that an object $F$ has mixed weight $w(F) \leq w$ means that for every point $y \in Y$ which is fixed by $Fr^n$ ($n > 0$) and for every $i \in \mathbb{Z}$ the absolute value of the eigenvalues of $Fr^n$ acting on the $i$-th cohomology (4.3.6) satisfy

$$
\left| e.v(Fr^n_{|H^i(F_y)}) \right| \leq \sqrt{p}(w+i).
$$

(In the precise definition it is also required that the cohomology sheaves of $F$ are mixed in the sense of [8, (1.2.2)], [27, I (2.1)].) In our case $w = 0$ and therefore

$$
\left| e.v(Fr^n_{|H^i(F_y)}) \right| \leq \sqrt{p}^i.
$$

Property 2 of Theorem 4.4 concerns a function $f^F : Y \longrightarrow \mathbb{C}$ associated to the sheaf $F$. To define $f^F$, we only have to describe its value at every point $y \in Y$. For a given $y \in Y$ the Frobenius acts on the cohomologies of the fiber
In other words, the value $f^F(y)$ is the alternating sum of traces of the operator $Fr$ acting on the cohomologies of the fiber $F_y$. This alternating sum is called the *Euler characteristic* of Frobenius and it is denoted by

$$f^F(y) = \chi_{Fr}(F_y).$$

Theorem 4.4 confirms that $f^F$ is the trace function $F$ defined earlier by formula (4.2.1). Associating the function $f^F$ on the set $Y_{Fr}$ to the sheaf $F$ on $Y$ is a particular case of a general procedure called *Sheaf-to-Function Correspondence* [14]. As this procedure will be used later, we shall now explain it in greater detail (cf. [12]).

**Grothendieck’s Sheaf-To-Function correspondence.** Let $X$ be an algebraic variety defined over $\mathbb{F}_q$. Let $\mathcal{L} \in D^b_c(X)$ be a Weil sheaf. One can associate to $\mathcal{L}$ a function $f^\mathcal{L}$ on the set $X$ by the following formula:

$$f^\mathcal{L}(x) = \sum_{i \in \mathbb{Z}} (-1)^i \text{Tr} \left( Fr \bigg|_{H^i(\mathcal{L}_x)} \right).$$

This procedure is called Sheaf-To-Function correspondence. Next, we describe some important functorial properties of this procedure.

Let $X_1$, $X_2$ be algebraic varieties defined over $\mathbb{F}_q$. Let $X_1 = X_{1Fr}$ and $X_2 = X_{2Fr}$ be the corresponding sets of rational points. Let $\pi : X_1 \to X_2$ be a morphism of algebraic varieties. Denote also by $\pi : X_1 \to X_2$ the induced map on the level of sets.

**First statement.** Suppose we have a Weil sheaf $\mathcal{L} \in D^b_c(X_2)$. The following holds:

$$f^{\pi^*(\mathcal{L})} = \pi^*(f^\mathcal{L}),$$

where on the function level $\pi^*$ is just the pull-back of functions. On the sheaf theoretic level $\pi^*$ is the pull-back functor of sheaves (think of pulling back a vector bundle). Equation (4.3.8) states that the Sheaf-to-Function Correspondence commutes with the operation of pull-back.

**Second statement.** Suppose we have a Weil sheaf $\mathcal{L} \in D^b_c(X_1)$. The following holds:

$$f^{\pi_!(\mathcal{L})} = \pi_!(f^\mathcal{L}),$$

where on the function level, $\pi_!$ means to sum up the values of the function along the fibers of the map $\pi$. On the sheaf theoretic level, $\pi_!$ is a compact integration of sheaves (here we have no analogue under the vector bundle interpretation).
Equation (4.3.9) states that the Sheaf-to-Function Correspondence commutes with integration.

Third statement. Suppose we have two Weil sheaves $L_1, L_2 \in D^b_c(X_1)$. The following holds:

\[(4.3.10) \quad f^{L_1 \otimes L_2} = f^{L_1} \cdot f^{L_2}.\]

In other words, Sheaf-to-Function Correspondence takes the tensor product of sheaves to multiplication of the corresponding functions.

4.4. Geometric statement. Fix a nonzero element $\xi \in \Lambda^*$ and a sufficiently large prime $p$ so that $\xi \pmod p$ is not a $T_A$-eigenvector.\(^{11}\) We denote by $i_\xi$ the inclusion map $i_\xi : T_A \times \xi \rightarrow Y$. Returning to Theorem 4.2 and putting its contents in a functorial notation, we write the following inequality:

\[
\left| \text{pr}_!(i_\xi^*(F) \cdot \chi) \right| \leq 2\sqrt{p}.
\]

In other words, take the function $F : Y \rightarrow \mathbb{C}$ and

- Restrict $F$ to $T_A \times \xi$ and get $i_\xi^*(F)$.
- Multiply $i_\xi^*F$ by the character $\chi$ to get $i_\xi^*(F) \cdot \chi$.
- Integrate $i_\xi^*(F) \cdot \chi$ to the point, i.e., sum up all its values, and get a scalar $a_\chi = \text{pr}_!(i_\xi^*(F) \cdot \chi)$. Here pr stands for the projection $\text{pr} : T_A \times \xi \rightarrow \text{pt}$.

Then Theorem 4.2 asserts that the scalar $a_\chi$ is of an absolute value at most $2\sqrt{p}$.

Repeat the same steps in the geometric setting. We denote again by $i_\xi$ the closed imbedding $i_\xi : T_A \times \xi \rightarrow Y$. Take the sheaf $\mathcal{F}$ on $Y$ and apply the following sequence of operations:

- Pull-back $\mathcal{F}$ to the closed subvariety $T_A \times \xi$ and get the sheaf $i_\xi^*(\mathcal{F})$.
- Take the tensor product of $i_\xi^*(\mathcal{F})$ with the Kummer sheaf $\mathcal{L}_\chi$ and get $i_\xi^*(\mathcal{F}) \otimes \mathcal{L}_\chi$.
- Integrate $i_\xi^*(\mathcal{F}) \otimes \mathcal{L}_\chi$ to the point and get the sheaf $\text{pr}_!(i_\xi^*(\mathcal{F}) \otimes \mathcal{L}_\chi)$ on the point.

The operation of Sheaf-to-Function Correspondence commutes both with pullback (4.3.8), with integration (4.3.9) and takes the tensor product of sheaves to the multiplication of functions (4.3.10). This means that it intertwines the operations carried out on the level of sheaves with those carried out on the level of functions. The following diagram describes pictorially what has been

\(^{11}\)Note that this can be done for every nonzero $\xi \in \Lambda^*$ due the fact that $A \in \text{SL}_2(\mathbb{Z})$ is a hyperbolic element and does not have nonzero eigenvectors in $\Lambda^*$. 
stated so far:
\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\chi_{\text{Fr}}} & \mathcal{F} \\
\downarrow i_{\xi} & & \downarrow i_{\xi} \\
i_{\xi}^*(\mathcal{F}) \otimes \mathcal{L}_\chi & \xrightarrow{\chi_{\text{Fr}}} & i_{\xi}^*(\mathcal{F}) \cdot \chi \\
\downarrow \text{pr} & & \downarrow \text{pr} \\
\text{pr}_!(i_{\xi}^*(\mathcal{F}) \otimes \mathcal{L}_\chi) & \xrightarrow{\chi_{\text{Fr}}} & \text{pr}_!(i_{\xi}^*(\mathcal{F}) \cdot \chi).
\end{array}
\]

Recall the weight property \( w(\mathcal{F}) \leq 0 \). Now, the effect of the functors \( i_{\xi}^* \), \( \text{pr}_! \) and tensor product \( \otimes \) on the property of weight should be examined.

The functor \( i_{\xi}^* \) does not increase weight. When we observe the definition of weight, this claim is immediate. Therefore, we get
\[
w(i_{\xi}^*(\mathcal{F})) \leq 0.
\]

Assume we have two Weil objects \( \mathcal{L}_1 \) and \( \mathcal{L}_2 \) of mixed weights \( w(\mathcal{L}_1) \leq w_1 \) and \( w(\mathcal{L}_2) \leq w_2 \). Then the tensor product \( \mathcal{L}_1 \otimes \mathcal{L}_2 \) is of mixed weight \( w(\mathcal{L}_1 \otimes \mathcal{L}_2) \leq w_1 + w_2 \). This is again immediate from the definition of weight.

Knowing that the Kummer sheaf has pure weight \( w(\mathcal{L}_\chi) = 0 \), we deduce
\[
w(i_{\xi}^*(\mathcal{F}) \otimes \mathcal{L}_\chi) \leq 0.
\]

Finally, one has to understand the effect of the functor \( \text{pr}_! \). The following theorem, proposed by Deligne [9], is a very deep and important result in the theory of weights. Briefly speaking, the theorem states that compact integration of sheaves does not increase weight. Here is the precise statement:

**Theorem 4.5** (Deligne, Weil II [9]). Let \( \pi : \mathbf{X}_1 \rightarrow \mathbf{X}_2 \) be a morphism of algebraic varieties. Let \( \mathcal{L} \in \text{D}^{b}_{\text{c}}(\mathbf{X}_1) \) be a Weil object of mixed weight \( w(\mathcal{L}) \leq w \); then the sheaf \( \pi_!(\mathcal{L}) \) is of mixed weight \( w(\pi_!(\mathcal{L})) \leq w \).

Using Theorem 4.5 we get
\[
w(\text{pr}_!(i_{\xi}^*(\mathcal{F}) \otimes \mathcal{L}_\chi)) \leq 0.
\]

Consider the sheaf \( \mathcal{G} = \text{pr}_!(i_{\xi}^*(\mathcal{F}) \otimes \mathcal{L}_\chi) \). It is a Weil object in \( \text{D}^{b}_{\text{c}}(pt) \). This means it is merely a complex of vector spaces, \( \mathcal{G} = \mathcal{G}^* \), together with an action of Frobenius
\[
\cdots \xrightarrow{d} \mathcal{G}^{-1} \xrightarrow{d} \mathcal{G}^0 \xrightarrow{d} \mathcal{G}^1 \xrightarrow{d} \cdots \\
\downarrow \text{Fr} \quad \downarrow \text{Fr} \quad \downarrow \text{Fr} \\
\cdots \xrightarrow{d} \mathcal{G}^{-1} \xrightarrow{d} \mathcal{G}^0 \xrightarrow{d} \mathcal{G}^1 \xrightarrow{d} \cdots .
\]
The complex $G^*$ is associated by Sheaf-To-Function correspondence to the scalar $a_\chi$

\begin{equation}
(4.4.1) \quad a_\chi = \sum_{i \in \mathbb{Z}} (-1)^i \text{Tr}\left( F_T\big|_{H^i(G)} \right).
\end{equation}

Finally, we can give the geometric statement about $G$, which will imply Theorem 4.2.

**Lemma 4.6 (Vanishing Lemma).** Let $\mathcal{G} = \text{pr}_! (i^*_\xi (\mathcal{F} \otimes \mathcal{L}_\chi))$, where $\xi$ is not a $T_A$-eigenvector. All cohomologies $H^i(\mathcal{G})$ vanish except for $i = 1$. Moreover, $H^1(\mathcal{G})$ is a two-dimensional vector space.

Theorem 4.2 now follows easily. By Lemma 4.6 only the first cohomology $H^1(\mathcal{G})$ does not vanish and it is two-dimensional. Having $\text{Perv}(\mathcal{G}) \leq 0$ implies (by (4.3.7)) that the eigenvalues of Frobenius acting on $H^1(\mathcal{G})$ are of absolute value $\leq \sqrt{p}$. Hence, using formula (4.4.1) we get

$$|a_\chi| \leq 2\sqrt{p}.$$ 

The remainder of this section is devoted to the proof of Lemma 4.6.

4.5. **Proof of the Vanishing Lemma.** The proof will be given in several steps.

*Step 1.* We use the identifications (4.3.1), and (4.3.2). Note that all tori in $\text{SL}_2$ are conjugate. Therefore, there exists an element $S \in \text{SL}_2$ conjugating the Hecke torus $T_A \subset \text{SL}_2$ with the standard torus $T$

$$ST_A S^{-1} = T.$$ 

The situation is displayed in the following diagram

\[
\begin{array}{ccc}
\text{SL}_2 \times \mathbb{A}^2 & \xrightarrow{\alpha_S} & \text{SL}_2 \times \mathbb{A}^2 \\
\uparrow i_{\xi} & & \uparrow i_{\eta} \\
T_A \times \xi & \xrightarrow{\alpha_S} & T \times \eta \\
\downarrow \text{pr} & & \downarrow \text{pr} \\
\text{pt} & = & \text{pt}
\end{array}
\]

where $\eta = S \cdot \xi$ and $\alpha_S$ is the restriction of the action $\alpha$ to the element $S$.

*Step 2.* Using the equivariance property of the sheaf $\mathcal{F}$ (see Theorem 4.4, Property 3) we will show that it is sufficient to prove the Vanishing Lemma for the sheaf $\mathcal{G}_{st} = \text{pr}_!(i^*_\eta \mathcal{F} \otimes \alpha_{S!} \mathcal{L}_\chi)$. Indeed, we have

\begin{equation}
(4.5.1) \quad \mathcal{G} = \text{pr}_!(i^*_\xi \mathcal{F} \otimes \mathcal{L}_\chi) \simeq \text{pr}_! \alpha_{S_1!} (i^*_\xi \mathcal{F} \otimes \mathcal{L}_\chi).
\end{equation}
The morphism $\alpha_S$ is an isomorphism. Therefore, $\alpha_{S!}$ commutes with taking $\otimes$; hence we obtain

$$\text{pr}_1 \alpha_S(i^*_\xi(F) \otimes L_\chi) \simeq \text{pr}_1(\alpha_{S!}(i^*_\xi F) \otimes \alpha_{S!}(L_\chi)).$$

Applying base change we obtain

$$\alpha_{S!} i^*_\xi \mathcal{F} \simeq i^*_\eta \alpha_{S!} \mathcal{F}.$$  

Now using the equivariance property of the sheaf $\mathcal{F}$ we have the isomorphism

$$\alpha_{S!} \mathcal{F} \simeq \mathcal{F}.$$  

Combining (4.5.1), (4.5.2), (4.5.3) and (4.5.4) we get

$$\text{pr}_1(i^*_\xi \mathcal{F} \otimes L_\chi) \simeq \text{pr}_1(i^*_\eta \mathcal{F} \otimes \alpha_{S!} L_\chi).$$  

Therefore, we see from (4.5.5) that it is sufficient to prove vanishing of cohomologies for

$$\mathcal{G}_{st} = \text{pr}_1(i^*_\eta \mathcal{F} \otimes \alpha_{S!} L_\chi).$$

However, this is a situation over the standard torus and we can compute explicitly all the sheaves involved.

**Step 3.** The Vanishing Lemma holds for the sheaf $\mathcal{G}_{st}$. What remains is to compute (4.5.6). We write $\eta = (\lambda, \mu)$. The object $i^*_\eta \mathcal{F}$ vanishes at the identity of $T$ (the corresponding thing for the numerical function $F$ follows from Definition (4.2.1). It is easily verified from the construction in the appendix (see formulas (B.3.1) and (A.5.17)) that $\mathcal{F}$ vanishes on (identity of $T \times (V - 0)$.

By Theorem 4.4, Property 4, we have $i^*_\eta \mathcal{F} \simeq \mathcal{L}_\psi(\frac{a}{2} \frac{n}{n+1} \lambda, \mu) \otimes \mathcal{L}_{\sigma(a)}$, where $a$ is the coordinate of the standard torus $T$ and $\lambda \cdot \mu \neq 0$. The sheaf $\alpha_{S!} L_\chi$ is a character sheaf on the torus $T$. Hence, we get that (4.5.6) is a kind of a Kloosterman-sum sheaf. A direct computation (Appendix B, §B.4) proves the Vanishing Lemma for this sheaf. This completes the proof of the Hecke quantum unique ergodicity conjecture.

**Comment.** We remark that using the invariant formula for the sheaf $\mathcal{F}$ (see Formula (4.3.4)), one can obtain an alternative proof of the Vanishing Lemma. Noting that the invariant formula is valid on the open subvariety $\Omega \times V \subset Sp \times V$, which contains $T^x_A \times V$, the statement can be proved directly, without the use of the equivariance property, and with essentially the same cohomological computations.

---

12Recall that $\eta$ is not a $T$-eigenvector.
Appendix

Appendix A. Metaplectique

In the first part of this appendix we give a new construction of the Weil metaplectic representation \((\rho, \text{Sp}(V), \mathcal{H}_V)\), attached to a two-dimensional symplectic vector space \((V, \omega)\) over \(F_q\), which appears in the body of the paper. The difference is that here the construction is slightly more general. Even more importantly, it is obtained in completely natural geometric terms. The focal step in our approach is the introduction of a canonical Hilbert space on which the Weil representation is naturally manifested. The motivation to look for this space was initiated by a question of Kazhdan [21]. The key idea behind this construction was suggested to us by Bernstein [2]. The upshot is to replace the notion of a Lagrangian subspace by a more refined notion of an oriented Lagrangian subspace.\(^\text{13}\)

In the second part of this appendix we apply a geometrization procedure to the construction given in the first part, meaning that all sets are replaced by algebraic varieties and all functions are replaced by \(\ell\)-adic sheaves. This part is based on a letter of Deligne to Kazhdan from 1982 [10]. We extract from that work only the part that is most relevant to this paper. Although all basic ideas appear already in the letter, we tried to give here a slightly more general and detailed account of the construction. As far as we know, the contents of this mathematical work have never been published. This might be a good enough reason for writing this part.

The following is a description of the appendix. In Section A.1 we introduce the notion of oriented Lagrangian subspace and the construction of the canonical Hilbert space. In Section A.2 we obtain a natural realization of the Weil representation. In Section A.3 we give the standard Schrödinger realization (cf. [13], [18], [37]). We also include several formulas for the kernels of basic operators. These formulas will be used in Section A.4 where the geometrization procedure is described. In Section A.5 we give proofs of all lemmas and propositions which appear in previous sections.

For the remainder of the appendix we fix the following notation. Let \(F_q\) denote the finite field of characteristic \(p \neq 2\) and \(q\) elements. Fix \(\psi : F_q \to \mathbb{C}^*\) a nontrivial additive character. Denote by \(\sigma : F_q^* \to \mathbb{C}^*\) the Legendre multiplicative quadratic character. In some places in the appendix \(\sigma\) is extended to \(F_q\) by \(\sigma(0) = 0\) and the corresponding Kummer sheaf \(\mathcal{L}_\sigma\) is extended to the affine line by extension by zero.

\(^{13}\)We thank A. Polishchuk for pointing out to us that this is an \(F_q\)-analogue of well known considerations, due to Lion and Vergne [28], with usual oriented Lagrangians giving explicitly the metaplectic covering of \(\text{Sp}(2n, \mathbb{R})\).
A.1. Canonical Hilbert space.

A.1.1. Oriented Lagrangian subspace. Let \((V, \omega)\) be a two-dimensional symplectic vector space over \(\mathbb{F}_q\).

Definition A.1 (Bernstein [2]). An oriented Lagrangian subspace is a pair \((L, \varrho_L)\), where \(L\) is a Lagrangian subspace of \(V\) and \(\varrho_L : L - \{0\} \to \{\pm 1\}\) is a function which satisfies the following equivariant property:

\[
\varrho_L (t \cdot l) = \sigma(t) \varrho_L (l),
\]
where \(t \in \mathbb{F}_q^*\) and \(\sigma\) is the Legendre character of \(\mathbb{F}_q^*\).

We denote by \(\operatorname{Lag}^\circ\) the space of oriented Lagrangian subspaces. There is a forgetful map \(\operatorname{Lag}^\circ \to \operatorname{Lag}\), where \(\operatorname{Lag}\) is the space of Lagrangian subspaces, \(\operatorname{Lag} \simeq \mathbb{P}^1(\mathbb{F}_q)\). In the sequel we use the notation \(L^\circ\) to specify that \(L\) is equipped with an orientation.

A.1.2. The Heisenberg group. Let \(H\) be the Heisenberg group. As a set we have \(H = V \times \mathbb{F}_q\). The multiplication is defined by the following formula:

\[
(v, \lambda) \cdot (v', \lambda') = (v + v', \lambda + \lambda' + \frac{1}{2} \omega(v, v')).
\]

We have a projection \(\pi : H \to V\) and fix a section of this projection (A.1.1)

\[
s : V \to H, \quad s(v) = (v, 0).
\]

A.1.3. Models of irreducible representation. Given \(L^\circ = (L, \varrho_L) \in \operatorname{Lag}^\circ\), we construct the Hilbert space \(\mathcal{H}_{L^\circ} = \operatorname{Ind}^H_L \mathbb{C}_{\tilde{\psi}}\), where \(\tilde{L} = \pi^{-1}(L)\) and \(\tilde{\psi}\) is the extension of the additive character \(\psi\) to \(\tilde{L}\), using the section \(s\); i.e., \(\tilde{\psi} : \tilde{L} = L \times \mathbb{F}_q \to \mathbb{C}^*\) is given by the formula

\[
\tilde{\psi}(l, \lambda) = \psi(\lambda).
\]

More concretely, \(\mathcal{H}_{L^\circ} = \{f : H \to \mathbb{C} \mid f(\lambda h) = \psi(\lambda) f(h)\}\). The group \(H\) acts on \(\mathcal{H}_{L^\circ}\) by multiplication from the right. We have the following theorem (cf. [30]):

Theorem A.2 (Stone-von Neumann-Mackey). For an oriented Lagrangian subspace \(L^\circ\), the representation \(\mathcal{H}_{L^\circ}\) of \(H\) is irreducible. Moreover, for any two oriented Lagrangians \(L_1^\circ, L_2^\circ \in \operatorname{Lag}^\circ\) one has \(\mathcal{H}_{L_1^\circ} \simeq \mathcal{H}_{L_2^\circ}\) as representations of \(H\).

A.1.4. Canonical intertwining operators. Let \(L_1^\circ, L_2^\circ \in \operatorname{Lag}^\circ\) be two oriented Lagrangians. Let \(\mathcal{H}_{L_1^\circ}, \mathcal{H}_{L_2^\circ}\) be the corresponding representations of \(H\). We denote by \(\operatorname{Int}_{L_2^\circ, L_1^\circ} = \operatorname{Hom}_H(\mathcal{H}_{L_1^\circ}, \mathcal{H}_{L_2^\circ})\) the space of intertwining operators between the two representations. Because all representations are irreducible
and isomorphic to each other we have \( \dim(\text{Int}_{L_2^\circ, L_1^\circ}) = 1 \). Next, we construct a canonical element in \( \text{Int}_{L_2^\circ, L_1^\circ} \).

Let \( L_1^\circ = (L_1, \theta_{L_1}) \), \( L_2^\circ = (L_2, \theta_{L_2}) \) be two oriented Lagrangian subspaces. Assume they are in general position, i.e., \( L_1 \neq L_2 \). We define the following specific element \( F_{L_2^\circ, L_1^\circ} \in \text{Int}_{L_2^\circ, L_1^\circ} \). \( F_{L_2^\circ, L_1^\circ} : \mathcal{H}_{L_1^\circ} \rightarrow \mathcal{H}_{L_2^\circ} \). By the following formula:

\[
(A.1.2) \quad F_{L_2^\circ, L_1^\circ} = a_{L_2^\circ, L_1^\circ} \cdot \tilde{F}_{L_2^\circ, L_1^\circ},
\]

where \( \tilde{F}_{L_2^\circ, L_1^\circ} : \mathcal{H}_{L_1^\circ} \rightarrow \mathcal{H}_{L_2^\circ} \) denotes the standard averaging operator and \( a_{L_2^\circ, L_1^\circ} \) denotes the normalization factor. The formulas are

\[
\tilde{F}_{L_2^\circ, L_1^\circ}(f)(h) = \sum_{l_2 \in L_2} f(l_2 h),
\]

where \( f \in \mathcal{H}_{L_1^\circ} \) and

\[
a_{L_2^\circ, L_1^\circ} = \frac{1}{q_{L_1}} \sum_{l_1 \in L_1} \psi(\frac{1}{2} \omega(l_1, \xi_{L_2})) \theta_{L_1}(l_1) \theta_{L_2}(\xi_{L_2}),
\]

where \( \xi_{L_2} \) is a fixed nonzero vector in \( L_2 \). Note that \( a_{L_2^\circ, L_1^\circ} \) does not depend on \( \xi_{L_2} \).

Now we extend the definition of \( F_{L_2^\circ, L_1^\circ} \) to the case where \( L_1 = L_2 \). Define

\[
F_{L_2^\circ, L_1^\circ} = \begin{cases} I, & \theta_{L_1} = \theta_{L_2} \\ -I, & \theta_{L_1} = -\theta_{L_2} \end{cases}
\]

The main claim is that the collection \( \{F_{L_2^\circ, L_1^\circ}\}_{L_1^\circ, L_2^\circ \in \text{Lag}^\circ} \) is associative. This is formulated in the following theorem:

**Theorem A.3 (Associativity).** Let \( L_1^\circ, L_2^\circ, L_3^\circ \in \text{Lag}^\circ \) be a triple of oriented Lagrangian subspaces. The following associativity condition holds:

\[
F_{L_3^\circ, L_1^\circ} \circ F_{L_2^\circ, L_1^\circ} = F_{L_3^\circ, L_2^\circ}.
\]

For a proof, see Section A.5.

A.1.5. **Canonical Hilbert space.** Define the canonical Hilbert space \( \mathcal{H}_V \subset \bigoplus_{L^\circ \in \text{Lag}^\circ} \mathcal{H}_{L^\circ} \) as the subspace of compatible systems of vectors, i.e.,

\[
\mathcal{H}_V = \left\{ (f_{L^\circ})_{L^\circ \in \text{Lag}^\circ} : F_{L_2^\circ, L_1^\circ}(f_{L_1^\circ}) = f_{L_2^\circ} \right\}.
\]

A.2. **The Weil representation.** In this section we construct the Weil representation using the Hilbert space \( \mathcal{H}_V \). We denote by \( \text{Sp} = \text{Sp}(V, \omega) \) the group of linear symplectomorphisms of \( V \). Before giving any formulas, note that the space \( \mathcal{H}_V \) was constructed out of the symplectic space \( (V, \omega) \) in a canonical way. This immediately implies that all the symmetries of \( (V, \omega) \) automatically
SHAMGAR GUREVICH and RONNY HADANI

act on $\mathcal{H}_V$. In particular, we obtain a linear representation of the group $\text{Sp}$ in the space $\mathcal{H}_V$. This is the famous Weil representation of $\text{Sp}$ and we denote it by $\rho : \text{Sp} \rightarrow \text{GL}(\mathcal{H}_V)$. It is given by the following formula:

(A.2.1) \[ \rho(g)(f_{L^0}) = (f^g_{L^0}). \]

Let us elaborate on this formula. The group $\text{Sp}$ acts on the space $\text{Lag}^\circ$. Any element $g \in \text{Sp}$ induces an automorphism $g : \text{Lag}^\circ \rightarrow \text{Lag}^\circ$ defined by \( (L, \varrho^L) \mapsto (gL, \varrho^gL) \), where $\varrho^gL(l) = \varrho^L(g^{-1}l)$. Moreover, $g$ induces an isomorphism of vector spaces $g : \mathcal{H}_{L^0} \rightarrow \mathcal{H}_{gL^0}$ defined by the following formula:

(A.2.2) \[ f_{L^0} \mapsto f^g_{L^0}, \quad f^g_{L^0}(h) = f_{L^0}(g^{-1}h), \]

where the action of $g \in \text{Sp}$ on $h = (v, \lambda) \in \mathcal{H}$ is given by $g(v, \lambda) = (gv, \lambda)$. It is easy to verify that the action (A.2.2) of $\text{Sp}$ commutes with the canonical intertwining operators; that is, for any two $L_1^\circ, L_2^\circ \in \text{Lag}^\circ$ and any element $g \in \text{Sp}$ the following diagram is commutative:

\[
\begin{array}{ccc}
\mathcal{H}_{L_1^0} & \xrightarrow{F_{L_1^0}L_2^0} & \mathcal{H}_{L_2^0} \\
g \downarrow & & g \downarrow \\
\mathcal{H}_{gL_1^0} & \xrightarrow{F_{gL_1^0}gL_2^0} & \mathcal{H}_{gL_2^0} \\
\end{array}
\]

From this we deduce that formula (A.2.1) indeed gives the action of $\text{Sp}$ on $\mathcal{H}_V$.

A.3. Realization and formulas. In this section we give the standard Schrödinger realization of the Weil representation. Several formulas for the kernels of basic operators are also included.

A.3.1. Schrödinger realization. Fix $V = V_1 \oplus V_2$ to be a Lagrangian decomposition of $V$. Fix $\varrho_{V_2}$ to be an orientation on $V_2$. Denote by $V_2^o = (V_2, \varrho_{V_2})$ the oriented space. Using the system of canonical intertwining operators we identify $\mathcal{H}_V$ with a specific representative $\mathcal{H}_{V_2^0}$. Using the section $s : V \rightarrow \mathcal{H}$ (cf. A.1.1) we further make the identification $s : \mathcal{H}_{V_2^0} \simeq S(V_1)$, where $S(V_1)$ is the space of complex valued functions on $V_1$. We denote $\mathcal{H} = S(V_1)$. In this realization the Weil representation, $\rho : \text{Sp} \rightarrow \text{GL}(\mathcal{H})$, is given by the following formula:

\[ \rho(g)(f) = F_{V_2^0,gV_2^o}(f^g), \]

where $f \in \mathcal{H} \simeq \mathcal{H}_{V_2^o}$ and $g \in \text{Sp}$. 
A.3.2. Formulas for the Weil representation. First we introduce a basis 
\( e \in V_1 \) and the dual basis \( e^* \in V_2 \) normalized so that \( \omega(e, e^*) = 1 \). In terms
of this basis we have the following identifications: 
\( V \simeq \mathbb{F}_q^2 \), \( V_1, V_2 \simeq \mathbb{F}_q \), 
\( \text{Sp} \simeq \text{SL}_2(\mathbb{F}_q) \) and \( \text{H} \simeq \mathbb{F}_q^2 \times \mathbb{F}_q \) (as sets). We also have \( \mathcal{H} \simeq \mathcal{S}(\mathbb{F}_q) \).

For every element \( g \in \text{Sp} \) the operator \( \rho(g) : \mathcal{H} \rightarrow \mathcal{H} \) is represented by a 
kernel \( K_g : \mathbb{F}_q^2 \rightarrow \mathbb{C} \). The multiplication of operators becomes a convolution 
of kernels. The collection \( \{K_g\}_{g \in \text{Sp}} \) gives a single function of “kernels” which 
we denote by \( K_\rho : \text{Sp} \times \mathbb{F}_q^2 \rightarrow \mathbb{C} \). For every element \( g \in \text{Sp} \) the kernel \( K_\rho(g) \) is supported on some linear subspace \( V(g) \) of \( \mathbb{F}_q^2 \) and is, there, of the form
\[
K_\rho(g, x, y) = a_g \cdot \psi(R_g(x, y)),
\]
where \( a_g \) is a certain normalizing coefficient and \( R_g : V(g) \rightarrow \mathbb{F}_q \) is a quadratic 
function. Next, we give an explicit description of the kernels \( K_\rho(g) \).

Consider the (opposite) Bruhat decomposition \( \text{Sp} = B w B \cup B \) where
\[
B = \begin{pmatrix} * & * & * \\ * & * & * \\ * & * & * \end{pmatrix},
\]
and \( w = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) is the standard Weyl element. If \( g \in B w B \), then
\[
g = \begin{pmatrix} a & b \\ c & d \end{pmatrix},
\]
where \( b \neq 0 \). In this case we have
\[
a_g = \frac{1}{q} \sum_{t \in \mathbb{F}_q} \psi\left(\frac{b}{2}t\right)\sigma(t),
\]
\[
R_g(x, y) = \frac{-b^{-1}d}{2}x^2 + \frac{b^{-1} - c + ab^{-1}d}{2}xy - \frac{ab^{-1}}{2}y^2.
\]
Finally, we have
\[
K_\rho(g, x, y) = a_g \cdot \psi\left(\frac{-b^{-1}d}{2}x^2 + \frac{b^{-1} - c + ab^{-1}d}{2}xy - \frac{ab^{-1}}{2}y^2\right).
\]
If \( g \in B \), then
\[
g = \begin{pmatrix} a & 0 \\ r & a^{-1} \end{pmatrix}.
\]
In this case we have
\[
a_g = \sigma(a),
\]
\[
R_g(x, y) = \frac{-ra^{-1}}{2}x^2 \cdot \delta_{y = a^{-1}x}.
\]
Finally, we have
\[
(A.3.1) \quad K_\rho(g, x, y) = a_g \cdot \psi\left(\frac{-ra^{-1}}{2}x^2\right) \delta_{y = a^{-1}x}.
\]
A.3.3. Formulas for the Heisenberg representation. On $\mathcal{H}$ we also have a representation of the Heisenberg group $H$. We denote it by $\pi : H \rightarrow GL(\mathcal{H})$. For every element $h \in H$ we have a kernel $K_h : \mathbb{F}_q^2 \rightarrow \mathbb{C}$. We denote by $K_{\pi} : H \times \mathbb{F}_q^2 \rightarrow \mathbb{C}$ the function of kernels. For an element $h \in H$ the kernel $K_{\pi}(h)$ is supported on a one-dimensional affine subspace of $\mathbb{F}_q^2$ and has there the form $\psi(R_h(x, y))$ with $R_h$ affine. Here are the exact formulas: For an element $h = (q, p, \lambda)$,

\begin{equation}
R_h(x, y) = \left( \frac{pq}{2} + px + \lambda \right) \delta_{y = x + q},
\end{equation}

\begin{equation}
K_{\pi}(h, x, y) = \psi \left( \frac{pq}{2} + px + \lambda \right) \delta_{y = x + q}.
\end{equation}

A.3.4. Formulas for the representation of the Jacobi group. The representations $\rho : Sp \rightarrow GL(\mathcal{H})$ and $\pi : H \rightarrow GL(\mathcal{H})$ combine together to give a representation of the semi-direct product $G = Sp \rtimes H$. The group $G$ is sometimes referred in literature as the Jacobi group. We denote the total representation by $\rho \rtimes \pi : G \rightarrow GL(\mathcal{H}), \rho \rtimes \pi(g, h) = \rho(g) \cdot \pi(h)$. The representation $\rho \rtimes \pi$ is given by a kernel $K_{\rho \rtimes \pi} : G \times \mathbb{F}_q^2 \rightarrow \mathbb{C}$. We denote this kernel simply by $K$.

We give an explicit formula for the kernel $K$ only in the case where $(g, h) \in BwB \times H$, i.e.,

\[ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \]

where $b \neq 0$ and $h = (q, p, \lambda)$. In this case

\begin{align}
R(g, h, x, y) &= R_g(x, y - q) + R_h(y - q, y), \\
K(g, h, x, y) &= a_y \cdot \psi(R_g(x, y - q) + R_h(y - q, y)).
\end{align}

A.4. Deligne’s letter. In this section we geometrize (Theorem A.5) the total representation $\rho \rtimes \pi : G \rightarrow GL(\mathcal{H})$. First, we realize all finite sets as rational points of certain algebraic varieties. Beginning with the vector space, we take $V = V(\mathbb{F}_q)$. Next we replace all groups. We take $H = H(\mathbb{F}_q)$, where $H = V \times G_a$, $Sp = Sp(\mathbb{F}_q)$ and finally $G = G(\mathbb{F}_q)$, where $G = Sp \times H$. The second step is to replace the kernel $K = K_{\rho \rtimes \pi} : G \times \mathbb{F}_q^2 \rightarrow \mathbb{C}$ (see (A.3.4)) by a sheaf theoretic object. Recall that $K$ is a kernel of a representation and hence satisfies the multiplication property

\begin{equation}
(m, Id)^* K = p_{1}^* K * p_{2}^* K,
\end{equation}

where $m$ denotes the multiplication map, and $m \times Id : G \times G \times \mathbb{F}_q^2 \rightarrow G \times \mathbb{F}_q^2$ is given by $(g_1, g_2, x, y) \mapsto (g_1g_2, x, y)$. Finally, $p_1(g_1, g_2, x, y) = (g_1, x, y)$ are the projections on the first and second $G$-coordinate respectively. The right-hand
side of (A.4.1) is the convolution

\[ p_1^*K * p_2^*K(g_1, g_2, x, y) = \sum_{z \in \mathbb{F}_q} K(g_1, x, z) \cdot K(g_2, z, y). \]

In the sequel, we will usually suppress the $\mathbb{F}_q^2$ coordinates, writing $m : G \times G \to G$ and $p_i : G \times G \to G$. Moreover, to enhance the clarity of the notation, we will also suppress the projections $p_i$ in (A.4.1), yielding a much cleaner statement:

(A.4.2) \[ m^*K = K * K. \]

These conventions will continue to hold also in the geometric setting, which is exactly where we will go. We replace the kernel $K$ by Deligne's Weil representation sheaf [10]. This is an object $\mathcal{K} \in \mathcal{D}^b_c(G \times \mathbb{A}^2)$ that satisfies\(^\text{14}\) the analogue (to (A.4.2)) multiplication property

\[ m^*\mathcal{K} \cong \mathcal{K} * \mathcal{K}, \]

and its function is \[ f^*\mathcal{K} = \mathcal{K}. \]

The strategy. The method of constructing the Weil representation sheaf $\mathcal{K}$ is reminiscent to some extent to the construction of an analytic function via an analytic continuation. In the realm of perverse sheaves one uses the operation of pesrve extension (cf. [1]), or, maybe, preferably called in our context middle extension.\(^\text{15}\) The main idea is to construct, using formulas, an explicit irreducible (shifted) perverse sheaf $\mathcal{K}_O$ on a “good” open subvariety $O \subset G \times \mathbb{A}^2$ and then we obtain the sheaf $\mathcal{K}$ by perverse extension of $\mathcal{K}_O$ to the whole variety $G \times \mathbb{A}^2$.

A.4.2. Preliminaries. We use in our construction the identifications $(V, \omega) \simeq (\mathbb{A}^2, \omega_{\text{std}})$, and $\mathbf{Sp} \simeq \mathbf{SL}_2$. We denote by $\emptyset$ the open subvariety

\[ O = O_w \times H \times \mathbb{A}^2, \]

where $O_w$ denotes the (opposite) big Bruhat cell $BwB \subset \mathbf{SL}_2$.

In the sequel we will frequently make use of the character property (cf. [12], [7]) of the sheaves $\mathcal{L}_\psi$ and $\mathcal{L}_\sigma$; that is,

(A.4.3) \[ s^*\mathcal{L}_\psi \simeq \mathcal{L}_\psi \boxtimes \mathcal{L}_\psi, \]

(A.4.4) \[ m^*\mathcal{L}_\sigma \simeq \mathcal{L}_\sigma \boxtimes \mathcal{L}_\sigma, \]

\(^{14}\)However, in this paper we will prove a weaker property (see Theorem A.5) which is sufficient for our purposes.

\(^{15}\)We use this as a unified terminology for taking a perverse extension with respect to any chosen perverse $t$-structure.
where \( s : \mathbb{G}_a \times \mathbb{G}_a \to \mathbb{G}_a \) and \( m : \mathbb{G}_m \times \mathbb{G}_m \to \mathbb{G}_m \) denotes the addition and multiplication morphisms correspondingly; also \( \boxtimes \) means external tensor product of sheaves.

Finally, given a sheaf \( \mathcal{L} \) we use the notation \( \mathcal{L}[i] \) for the translation functors and the notation \( \mathcal{L}(i) \) for the \( i \)-th Tate twist.

**Construction of the sheaf \( K \).** In the first step we sheafify the kernel \( K_{\rho \circ \pi} \) of the total representation, when restricted to the set \( O = O_w \times H \times A^2 \), using the formula (A.3.4). We obtain a shifted Weil sheaf \( K_O \) on the open subvariety \( O = O_w \times H \times A^2 \),

\[
K_O = A_O \otimes \tilde{K}_O,
\]

where \( \tilde{K}_O \) is the sheaf of the nonnormalized kernels and \( A_O \) is the sheaf of the normalization coefficients. The sheaves \( \tilde{K}_O \) and \( A_O \) are constructed as follows. Define the morphism \( R : O_w \times H \times A^2 \to A^1 \) by formula (A.3.3) and let \( \text{pr} : O_w \times H \times A^2 \to O_w \) be the projection morphism on the \( O_w \) coordinate. Now take

\[
\tilde{K}_O = R^* \mathcal{L}_\psi, \quad A_O = \text{pr}^* A_{O_w},
\]

where

\[
A_{O_w}(g) = \int_{x \in A^1} \mathcal{L}_\psi(\frac{1}{2} bx) \otimes \mathcal{L}_{\sigma(x)}[2](1).
\]

Here \( g = (a \ b \ c \ d) \), and the notation \( \int_{x \in A^1} \) means integration with compact support along the \( A^1 \) fiber. Using [7] we have

**Observation A.4.** The sheaf \( K_O \) is geometrically irreducible \([\dim(G) + 1]\)-perverse of pure weight zero and its function agrees with \( K \) on \( O \), that is, \( f^{K_O} = K|_O \).

Let \( j \) denote the open imbedding \( j : O \to G \times A^2 \). We define the Weil representation sheaf \( K \) as the middle extension

(A.4.5)

\[
K = j_! K_O.
\]

We are now ready to state the main theorem of this section

**Theorem A.5 (Weil representation sheaf [10]).** The sheaf \( K \) is a geometrically irreducible \([\dim(G) + 1]\)-perverse Weil sheaf on \( G \times A^2 \), of pure weight \( \text{Perv}(K) = 0 \). The sheaf \( K \) satisfies the following properties:

1. (Function) The function associated to \( K \), by sheaf-to-function correspondence, is the Weil representation kernel \( f^K = K \).
2. (Multiplication) For every element \( g \in G \) there exist isomorphisms

\[
K|_g \ast K \simeq L^*_g(K) \quad \text{and} \quad K \ast K|_g \simeq R^*_g(K),
\]
where $K_{|g}$ denotes the restriction of $K$ to the closed subvariety $g \times \mathbb{A}^2$ and $R_g, L_g : G \rightarrow G$ are the morphisms of right and left multiplication by $g$ respectively.

For a proof, see Section A.5.

Remark. In Property 2 the notation $g \in G$ means that $g$ is a morphism $g : \text{Spec}(\mathbb{F}_p) \rightarrow G$. In fact a finer statement is true; namely, if $g \in G(\mathbb{F}_q)$, $q = p^n$, then $K_{|g} * K \simeq L_g^*(K)$ and $K * K_{|g} \simeq R_g^*(K)$ are isomorphisms of Weil sheaves on $G \times \mathbb{A}^2$, considered as an algebraic variety over $\mathbb{F}_q$.

A.5. Proofs. In this section we give the proofs for all technical facts that appeared in Part A of the appendix.

Proof of Theorem A.3. Before giving the proof, we introduce a structure which is inherent to configurations of triple Lagrangian subspaces. Let $L_1, L_2, L_3 \subset V$ be three Lagrangian subspaces which are in a general position. In our case, these are just three different lines in the plane. Then the space $L_j$ induces an isomorphism $r_{L_1, L_2} : L_2 \rightarrow L_1$, $i \neq j \neq k$, which is given by the rule $r_{L_1, L_2}(l_k) = l_i$, where $l_k + l_i \in L_j$.

The actual proof of the theorem will be given in two parts. In the first part we deal with the case where the three lines $L_1, L_2, L_2 \in \text{Lag}$ are in a general position. In the second part we deal with the case when two of the three lines are equal to each other.

Part 1 (General position). Let $L_1^*, L_2^*, L_3^* \in \text{Lag}^*$ be three oriented lines in a general position. Using the presentation (A.1.2) we can write

$$F_{L_1^*, L_2^*} \circ F_{L_2^*, L_1^*} = a_{L_3^*, L_2^*} \cdot a_{L_2^*, L_1^*} \cdot \tilde{F}_{L_3^*, L_2^*} \circ \tilde{F}_{L_2^*, L_1^*},$$

$$F_{L_1^*, L_1^*} = a_{L_3^*, L_1^*} \cdot \tilde{F}_{L_3^*, L_1^*}.$$

The result for Part 1 is a consequence of the following three simple lemmas (to be proved below):

**Lemma A.6.** The following equality holds:

$$\tilde{F}_{L_3^*, L_2^*} \circ \tilde{F}_{L_2^*, L_1^*} = C \cdot \tilde{F}_{L_3^*, L_1^*},$$

where $C = \sum_{l_2 \in L_2} \psi(\frac{1}{2} \omega(l_2, r_{L_3^*, L_2^*}(l_2)))$.

**Lemma A.7.** The following equality holds:

$$a_{L_3^*, L_2^*} \cdot a_{L_2^*, L_1^*} = D \cdot a_{L_3^*, L_1^*},$$

where $D = \frac{1}{q} \sum_{l_2 \in L_2} \psi(-\frac{1}{2} \omega(l_2, r_{L_3^*, L_2^*}(\xi_{L_2}))) \varrho_{L_2}(l_2) \varrho_{L_2}(\xi_{L_2})$.
Lemma A.8. The following equality holds:

\[ D \cdot C = 1. \]

Part 2 (Nongeneral position). It is sufficient to check the following equalities:

\[
\begin{align*}
\text{(A.5.1)} & \quad F_{L_1^\circ L_2^\circ} \circ F_{L_2, L_1^\circ} = I, \\
\text{(A.5.2)} & \quad F_{L_1^\circ L_2^\circ} \circ F_{L_2, L_1^\circ} = -I,
\end{align*}
\]

where \( L_1^\circ \) has the opposite orientation to \( L_1^\circ \). We verify equation (A.5.1). The verification of (A.5.2) is done in the same way, therefore we omit it.

Write

\[
\tilde{\Phi}_{L_1^\circ L_2^\circ} \left( \tilde{\Phi}_{L_2, L_1^\circ} (f) \right) (h) = \sum_{l_1 \in L_1} \sum_{l_2 \in L_2} f(l_2 l_1 h),
\]

where \( f \in \mathcal{H}_{L_1} \) and \( h \in H \). Both sides of (A.5.1) are self-intertwining operators of \( \mathcal{H}_{L_1} \) and therefore they are proportional. Hence, it is sufficient to compute (A.5.3) for a specific function \( f \) and a specific element \( h \in H \) such that \( f(h) \) is nonzero. We take \( h = 0 \) and \( f = \delta_0 \), where \( \delta_0(\lambda h) = \psi(\lambda) \) if \( h = 0 \) and equals 0 otherwise. We get

\[
\sum_{l_1 \in L_1} \sum_{l_2 \in L_2} f(l_2 l_1 h) = q.
\]

Now write

\[
a_{L_1^\circ L_2^\circ} \cdot a_{L_2, L_1^\circ} = \frac{1}{q^2} \sum_{l_1 \in L_1, l_2 \in L_2} \psi \left( \frac{1}{2} \omega(l_2, \xi_{L_1^\circ}) + \frac{1}{2} \omega(l_1, \xi_{L_2^\circ}) \right) \varrho_{L_2, l_1} \varrho_{L_1} \varrho_{l_2} \varrho_{\xi_1}.
\]

We identify \( L_2 \) and \( L_1 \) with the field \( F_q \) by the rules \( s \cdot 1 \mapsto s \cdot \xi_{L_2} \) and \( t \cdot 1 \mapsto t \cdot \xi_{L_1} \) correspondingly. In terms of these identifications we get

\[
\text{(A.5.4)} & \quad a_{L_1^\circ L_2^\circ} \cdot a_{L_2, L_1^\circ} = \frac{1}{q^2} \sum_{t, s \in F_q} \psi \left( \frac{1}{2} s \omega(\xi_{L_2}, \xi_{L_1}) + \frac{1}{2} t \omega(\xi_{L_1}, \xi_{L_2}) \right) \sigma(t) \sigma(s).
\]

Denote \( a = \omega(\xi_{L_2}, \xi_{L_1}) \). The right-hand side of (A.5.4) is equal to

\[
\frac{1}{q^2} \sum_{s \in F_q} \psi \left( \frac{1}{2} s a \sigma(s) \sum_{t \in F_q} \psi(- \frac{1}{2} at) \sigma(t) = \frac{q}{q^2} = \frac{1}{q}.
\]

Finally, we get

\[
F_{L_1^\circ L_2^\circ} \circ F_{L_2, L_1^\circ} = I.
\]
Proof of Lemma A.6. The proof is by direct computation. Write
\begin{align}
(A.5.5) \quad \tilde{F}_{L_3^o, L_1^o}^o(f)(h) &= \sum_{l_3 \in L_3} f(l_3 h), \\
(A.5.6) \quad \tilde{F}_{L_3^o, L_2^o}^o \left( \tilde{F}_{L_2^o, L_1^o}^o(f) \right)(h) &= \sum_{l_3 \in L_3} \sum_{l_2 \in L_2} f(l_2 l_3 h),
\end{align}

where \( f \in \mathcal{H}_{L_1} \) and \( h \in H \). Both (A.5.5) and (A.5.6) are intertwining operators from \( \mathcal{H}_{L_1} \) to \( \mathcal{H}_{L_3} \). Therefore they are proportional. In order to compute the proportionality coefficient \( C \) it is enough to compute (A.5.5) and (A.5.6) for specific \( f \) and specific \( e \). We take \( h = 0 \) and \( f = \delta_0 \), where \( \delta_0(q, p, \lambda) = \psi(\lambda) \), and get
\begin{align}
(A.5.7) \quad \tilde{F}_{L_3^o, L_1^o}^o(\delta_0) &= 1, \\
\quad \tilde{F}_{L_3^o, L_2^o}^o \left( \tilde{F}_{L_2^o, L_1^o}^o(\delta_0) \right)(0) &= \sum_{l_2 \in L_2} \psi \left( \frac{1}{2} \omega(l_2, r_{L_3, L_2}(l_2)) \right).
\end{align}

But the right-hand side of (A.5.7) is equal to
\[
\sum_{l_2 \in L_2} \psi \left( \frac{1}{2} \omega(l_2, r_{L_3, L_2}(l_2)) \right). \quad \square
\]

Proof of Lemma A.7. The proof is by direct computation. Write
\begin{align}
(a_{L_3^o, L_1^o} &\cdot a_{L_2^o, L_1^o})^o \\
&= \frac{1}{q^2} \sum_{l_1 \in L_1, l_2 \in L_2} \psi \left( \frac{1}{2} \omega(l_1, \xi_{L_2} - \xi_{L_1}) + \frac{1}{2} \omega(l_2, \xi_{L_3}) \right) q_{L_1}(l_1) q_{L_2}(\xi_{L_2}) q_{L_3}(\xi_{L_3}).
\end{align}

The term \( \psi \left( \frac{1}{2} \omega(l_1, \xi_{L_2}) + \frac{1}{2} \omega(l_2, \xi_{L_3}) \right) \) is equal to
\begin{align}
(A.5.9) \quad \psi \left( \frac{1}{2} \omega(l_1, \xi_{L_2} - \xi_{L_1}) + \frac{1}{2} \omega(l_2, \xi_{L_3}) \right) \cdot \psi \left( \frac{1}{2} \omega(l_1, \xi_{L_3}) \right).
\end{align}

We are free to choose \( \xi_{L_3} \) such that \( \xi_{L_2} - \xi_{L_3} \in L_1 \). Therefore, using (A.5.9) we get that the right-hand side of (A.5.8) is equal to
\begin{align}
(A.5.10) \quad \frac{1}{q} \sum_{l_2 \in L_2} \psi \left( \frac{1}{2} \omega(l_2, \xi_{L_3}) \right) q_{L_2}(\xi_{L_2}) q_{L_2}(l_2) a_{L_3^o, L_1^o}.
\end{align}

Now, substituting \( \xi_{L_3} = -r_{L_3, L_2}(\xi_{L_2}) \) in (A.5.10) we obtain
\begin{align}
\frac{1}{q} \sum_{l_2 \in L_2} \psi \left( -\frac{1}{2} \omega(l_2, r_{L_3, L_2}(\xi_{L_2})) \right) q_{L_2}(l_2) a_{L_3^o, L_1^o}. \quad \square
\end{align}
Proof of Lemma A.8. Identify $L_2$ with $F_q$ by the rule $t \cdot 1 \mapsto t \cdot \xi_{L_2}$. In terms of this identification we get

$$D = \frac{1}{q} \sum_{t \in F_q} \psi(- \frac{1}{2} \omega(t \xi_{L_2}, r_{L_2}) \varrho(t)),$$

$$C = \sum_{t \in F_q} \psi(\frac{1}{2} \omega(t \xi_{L_2}, r_{L_2})).$$

Denote by $a = \omega(\xi_{L_2}, r_{L_2})$. Then

$$D = \frac{1}{q} \sum_{t \in F_q} \psi(- \frac{1}{2} at) \varrho(t),$$

$$C = \sum_{t \in F_q} \psi(\frac{1}{2} at^2).$$

Now, we have the following remarkable equality:

$$\sum_{t \in F_q} \psi(\frac{1}{2} at) \varrho(t) = \sum_{t \in F_q} \psi(\frac{1}{2} at^2).$$

This, combined with $C \cdot \overline{C} = q$, gives the result.  

This completes the proof of Part 2 and of Theorem A.3.

Proof of Theorem A.5. The sheaf $K$ is obtained by middle extension from the open subvariety $O$ of the sheaf $K_O$. The sheaf $K_O$ is clearly geometrically irreducible $[\dim(G) + 1]$-perverse of pure weight 0. This implies that the sheaf $K$ is also geometrically irreducible $[\dim(G) + 1]$-perverse of pure weight $\text{Perv}(K) = 0$.

Proof of Property 1. Assuming the validity of Property 2, we prove Property 1. Restricting the sheaf $K$ to the open subvariety $O$, and taking sheaf-to-function correspondence, one obtains $f^K = f^{K_O} = K_{\{0\}}$. Applying sheaf-to-function correspondence to the multiplication isomorphism, we get that $f^K$ is multiplicative. Finally, we use the fact that the set $O_w \times H$ is a generating set of $G$. Therefore, we have two functions $K$ and $f^K$ that coincide on a generating set and satisfy the multiplication property. This implies that they must coincide on the whole domain.

Proof of Property 2. What remains is to prove the multiplication property, namely, Property 2. We will prove the left multiplication isomorphism. The proof of the right multiplication isomorphism follows the same lines; therefore we omit it. In the course of the proof we shall use the following auxiliary sheaves:
• We sheafify the kernel $K_\pi$ using the formula (A.3.2) and obtain a sheaf on $H \times \mathbb{A}^2$:
\begin{equation}
K_\pi(h, x, y) = \mathcal{L}_\psi(\frac{1}{2}pq + px + \lambda) \otimes \delta_{y = x + q},
\end{equation}
where $h = (q, p, \lambda)$, and we use the notation $\delta$ for the constant sheaf $\overline{\mathbb{Q}}_\ell$ on a subvariety extended by zero.

• We sheafify the kernel $K_\rho$ when restricted to the set $B \times F^2_q$ using the formula (A.3.1) and obtain a sheaf on the variety $B \times \mathbb{A}^2$, which we denote by $K_B$,
\begin{equation}
K_B(b, x, y) = \mathcal{L}_\sigma(a) \otimes \mathcal{L}_\psi(-\frac{1}{2}ra^{-1}x^2) \otimes \delta_{y = a^{-1}x},
\end{equation}
where $b = (\begin{smallmatrix} a & 0 \\ r & a^{-1} \end{smallmatrix})$.

• We will frequently make use of several other sheaves obtained by restrictions from $K_O$, $A_O$, $K_B$ and $A_B$. Suppose $X \subset O_w \times H$ is a subvariety. Then we define $K_X = K_{O|_{X \times \mathbb{A}^2}}$ and $A_X = A_{O|_{X \times \mathbb{A}^2}}$, the same when $X \subset B$. Finally, we denote by $\delta_0$ the sky-scraper sheaf on $\mathbb{A}^1$ which corresponds to the delta function at zero.

The proof of Property 2 will proceed in several steps:

**Step 1.** It is sufficient to prove the multiplication property separately for the Weyl element $w$, an element $b \in B$ and an element $h \in H$. This follows from the Bruhat decomposition, Corollary A.12 below and the following decomposition lemma.

**Lemma A.9.** There exist isomorphisms
\begin{equation}
K_O \simeq K_B \ast K_w \ast K_U \ast K_\pi,
\end{equation}
where $U$ denotes the unipotent radical of $B$ and $w$ is the Weyl element.

**Step 2.** We prove Property 2 for the Weyl element, $g = w$. We want to construct an isomorphism
\begin{equation}
K_{|w} \ast K \simeq L_w^* K.
\end{equation}
Both sides of (A.5.13) are irreducible $[\dim(G) + 1]$-perverse since $K_{|w} \ast$ is essentially a Fourier transform; therefore it is sufficient to construct an isomorphism on the open subvariety $O^x = O \cap wO$ where both sides are nonzero. This has the advantage that over $O^x$ we have formulas for $K$, and moreover, $L_w$ maps $O^x$ into itself. We consider two decompositions:
\begin{equation}
O^x \simeq U^x \times B \times H,
\end{equation}
\begin{equation}
O^x \simeq U^x w \times B \times H,
\end{equation}
where $U^x = U - \{I\}$ and $U^o$ denotes the unipotent radical of the standard Borel. In terms of the above decompositions we have the following isomorphisms:

**Claim A.10.** There exist isomorphisms

1. $K_{\mathcal{U}}(u^o bh) \simeq K_{U^x \times (u^o)} * K_{B}(b) * K_{\pi}(h)$,
2. $K_{\mathcal{U}}(uw bh) \simeq K_{U^x \times (uw)} * K_{B}(b) * K_{\pi}(h)$.

Now, when we restrict to $O^x$ and use the decomposition (A.5.14) our main statement is the existence of an isomorphism

(A.5.15) $K_w * K_{\mathcal{U}}(u^o bh) \simeq K_{\mathcal{U}}(wu^o bh)$.

Indeed, on developing the right-hand side of (A.5.15) we obtain

$$K_{\mathcal{U}}(wu^o bh) = K_{\mathcal{U}}(u^o w bh)$$
$$\simeq K_{U^x \times (u^o w)} * K_{B}(b) * K_{\pi}(h)$$
$$\simeq K_w * (K_{U^x \times (u^o)} * K_{B}(b) * K_{\pi}(h))$$
$$\simeq K_w * K_{\mathcal{U}}(u^o bh),$$

where $u^o w = wu^o w^{-1}$. The first and third isomorphisms are applications of Claim A.10, parts 2 and 1 respectively. The second isomorphism is a result of associativity of convolution and the following central lemma:

**Lemma A.11.** There exists an isomorphism

(A.5.16) $K_{U \times w}(u^o w) \simeq K_w * K_{U^x \times (u^o)}$.

The following is a consequence of (A.5.13).

**Corollary A.12.** There exists an isomorphism

(A.5.17) $K_{B \times H} \simeq K_B * K_{\pi}$.

*Proof.* On developing the left-hand side of (A.5.17) we obtain

$$K_{B \times H} \simeq K_w * K_{|w^{-1}B \times H}$$
$$\simeq K_w * (K_{w^{-1}} * K_B * K_{\pi})$$
$$\simeq (K_w * K_{w^{-1}}) * K_B * K_{\pi}$$
$$\simeq K_B * K_{\pi}.$$

The first isomorphism is a consequence of (A.5.13). The second isomorphism is a consequence of Lemma A.9. The third isomorphism is the associativity property of convolution. The last isomorphism is a property of the Fourier transform [20], that is, $K_w * K_{w^{-1}} \simeq I$, where $I$ is the kernel of the identity operator. □
Step 3. We prove Property 2 for element $b \in B$. Using Corollary A.12 we have $K_b \simeq K_{B_b} = K_b$. We want to construct an isomorphism

$$(A.5.18) \quad K_b \ast K \simeq L_b^*K.$$ 

Since both sides of (A.5.18) are irreducible (shifted) perverse sheaves, it is sufficient to construct an isomorphism on the open set $O = O_w \times H \times \mathbb{A}^2$. Write

$$K_b \ast K_{|O} \simeq K_b \ast K \simeq (K_b \ast K_{B} \ast K_{U} \ast K_{\pi}) \simeq (K_b \ast K_{B}) \ast (K_{U} \ast K_{\pi}).$$

The first isomorphism is by construction. The second isomorphism is an application of Lemma A.9. The third isomorphism is the associativity property of the convolution operation between sheaves. From the last isomorphism we see that it is enough to construct an isomorphism $K_b \ast K_{B} \simeq L_b^*(K_{B})$, where $L_b : B \rightarrow B$. The construction is an easy consequence of formula (A.3.1) and the character sheaf property (A.4.3) of $L_{\psi}$.

Step 4. We prove Property 2 for an element $h \in H$. We want to construct an isomorphism

$$(A.5.19) \quad K_{|h} \ast K \simeq L_h^*K.$$ 

Both sides of (A.5.19) are irreducible $[\dim(G) + 1]$- perverse. Therefore, it is sufficient to construct an isomorphism on the open set $O$. This is done by a direct computation, very similar to what has been done before, hence we omit it. This concludes the proof of Theorem A.5. □

Proof of Lemma A.9. We will prove the lemma in two steps.

Step 1. We prove that $K_{O} \simeq K_{O_w} \ast K_{\pi}$. In a more explicit form we want to show

$$(A.5.20) \quad \mathcal{A}_O \otimes \mathcal{K}_O \simeq \mathcal{A}_{O_w} \otimes \mathcal{K}_{O_w} \ast \mathcal{K}_H.$$ 

It is sufficient to show the existence of an isomorphism $\mathcal{K}_{O} \simeq \mathcal{K}_{O_w} \ast \mathcal{K}_H$. On developing the left-hand side of (A.5.20) we obtain

$$\mathcal{K}_{O}(g,h,x,y) = \mathcal{L}_{\psi}(R(g,h,x,y)).$$

On developing the right-hand side we obtain

$$\mathcal{K}_{O_w} \ast \mathcal{K}_H((g,h),x,y) = \int_{z \in \mathbb{A}^1} \mathcal{K}_{O_w}(g,x,z) \otimes \mathcal{K}_H(h,z,y)$$

$$= \int_{\mathbb{A}^1} \mathcal{L}_{\psi}(R_p(x,z)) \otimes \mathcal{L}_{\psi}(R_h(z,y)) \otimes \delta_{y = z - q}$$

$$\simeq \mathcal{L}_{\psi}(R_p(x,y - q)) \otimes \mathcal{L}_{\psi}(R_h(y - q, y))$$

$$\simeq \mathcal{L}_{\psi}(R_p(x,y - q) + R_h(y - q, y))$$

$$= \mathcal{L}_{\psi}(R(g,h,x,y)).$$
The only nontrivial isomorphism is the last one and it is a consequence of the Artin-Schreier sheaf being a character sheaf on the additive group $\mathbb{G}_a$.

Step 2. We prove that $\mathcal{K}_{O_w} \simeq \mathcal{K}_B \ast \mathcal{K}_w \ast \mathcal{K}_U$. In a more explicit form we want to show that

$$\mathcal{A}_{O_w} \otimes \tilde{\mathcal{K}}_{O_w} \simeq \mathcal{A}_B \otimes \mathcal{A}_w \otimes \mathcal{A}_U \otimes \tilde{\mathcal{K}}_B \ast \tilde{\mathcal{K}}_w \ast \tilde{\mathcal{K}}_U,$$

where $\mathcal{A}_B \otimes \tilde{\mathcal{K}}_B = \mathcal{K}_B$ with $\mathcal{A}_B(b) = L_{\sigma(a)}$ and $\tilde{\mathcal{K}}_B(b, x, y) = L_{\psi(-\frac{1}{2} r a^{-1} x^2)} \otimes \delta_{y=a^{-1}x}$ for a general element $b = \left( \begin{smallmatrix} a & 0 \\ r & a^{-1} \end{smallmatrix} \right)$ in the group $B$ (see (A.5.12)).

We will separately show the existence of two isomorphisms

(A.5.21) $\tilde{\mathcal{K}}_{O_w} \simeq \tilde{\mathcal{K}}_B \ast \tilde{\mathcal{K}}_w \ast \tilde{\mathcal{K}}_U$,

(A.5.22) $\mathcal{A}_{O_w} \simeq \mathcal{A}_B \otimes \mathcal{A}_w \otimes \mathcal{A}_U$.

Isomorphism (A.5.21). We have the decomposition, $O_w \simeq B \times w \times U$. Let $b = \left( \begin{smallmatrix} a & 0 \\ r & a^{-1} \end{smallmatrix} \right)$ and $u = \left( \begin{smallmatrix} 1 & 0 \\ s & 1 \end{smallmatrix} \right)$ be general elements in the groups $U$ and $B$ respectively. In terms of the coordinates $(a, r, s)$ a general element in $O_w$ is of the form $g = \left( \begin{smallmatrix} as & 0 \\ rs & a^{-1} \end{smallmatrix} \right)$. Developing the left-hand side of (A.5.21) in the coordinates $(a, r, s)$ we obtain

$$\tilde{\mathcal{K}}_{O_w}(bwu, x, y) = L_{\psi(-\frac{1}{2} a^{-1} r x^2 + a^{-1} y^2)}.$$

On developing the right-hand side of (A.5.21) we obtain

$$\tilde{\mathcal{K}}_B \ast \tilde{\mathcal{K}}_w \ast \tilde{\mathcal{K}}_U(bwu, x, y) = \int_{z, z' \in \mathbb{A}^1} \tilde{\mathcal{K}}_B(b, x, z) \otimes \tilde{\mathcal{K}}_w(w, z, z') \otimes \tilde{\mathcal{K}}_U(u, z', y)$$

$$= \int_{z, z' \in \mathbb{A}^1} L_{\psi(-\frac{1}{2} r a^{-1} x^2)} \otimes \delta_{x=a z} \otimes L_{\psi(z z')} \otimes L_{\psi(-\frac{1}{2} s z^2)} \otimes \delta_{y=z'}$$

$$\simeq L_{\psi(-\frac{1}{2} r a^{-1} x^2)} \otimes L_{\psi(a^{-1} y)} \otimes L_{\psi(-\frac{1}{2} s y^2)}$$

$$\simeq L_{\psi(-\frac{1}{2} r a^{-1} x^2 + a^{-1} y^2)}.$$

The last isomorphism is a consequence of the fact that the Artin-Schreier sheaf is a character sheaf (A.4.3). Finally, we obtain isomorphism (A.5.21).

Isomorphism (A.5.22). On developing the left-hand side of (A.5.22) in terms of the coordinates $(a, r, s)$ we obtain

$$\mathcal{A}_{O_w}(bwu) = G(\psi, \sigma)^{[2]}(1)$$

$$\simeq G(\psi, \sigma^{-1})^{[2]}(1)$$

$$\simeq L_{\sigma(a^{-1})} \otimes G(\psi, \sigma)^{[2]}(1)$$

$$\simeq L_{\sigma(a)} \otimes G(\psi, \sigma)^{[2]}(1)$$

$$= \mathcal{A}_B \otimes \mathcal{A}_w \otimes \mathcal{A}_U(bwu),$$
where $G(\psi, \sigma) = \int_{A^1} \mathcal{L}_\psi(\frac{1}{2} sz) \otimes \mathcal{L}_\sigma(az)$ denotes the quadratic Gauss-sum sheaf.

The second isomorphism is a change of coordinates $z \mapsto z/a$ under the integration. The third isomorphism is a consequence of the Kummer sheaf $\mathcal{L}_\sigma$ being a character sheaf on the multiplicative group $\mathbb{G}_m$ (A.4.4). The fourth isomorphism is a specific property of the Kummer sheaf which is associated to the quadratic character $\sigma$. This completes the construction of isomorphism (A.5.22).

**Proof of Claim A.10.** This is carried out in exactly the same way as the proof of the decomposition Lemma A.9: namely, by using the explicit formulas of the sheaves $\mathcal{K}_O, \mathcal{K}_B, \mathcal{K}_\pi$ and the character sheaf property of the sheaves $\mathcal{L}_\psi$ and $\mathcal{L}_\sigma$. □

**Proof of Lemma A.11.** First, we write isomorphism (A.5.16) in a more explicit form

\[(A.5.23) \quad A_{U^\times w} \otimes \tilde{K}_{U^\times w}(u^\circ w, x, y) \simeq A_w \otimes A_{U^\times w} \otimes \tilde{K}_w \ast \tilde{K}_{U^\circ w}(u^\circ).
\]

Let $u^\circ = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix} \in U^\times$ be a nontrivial unipotent. Then $u^\circ w = wu^\circ = \begin{pmatrix} 0 & 1 \\ -1 & -s \end{pmatrix}$.

On developing the left-hand side of (A.5.23) we obtain

\[
\tilde{K}_{U^\times w}(u^\circ w, x, y) = \mathcal{L}_\psi(\frac{1}{2} sx^2 + xy),
\]

\[
A_{U^\times w}(u^\circ w) = G(\psi, \sigma)[2](1),
\]

where $G(\psi, \sigma) = \int_{A^1} \mathcal{L}_\psi(\frac{1}{2} sz) \otimes \mathcal{L}_\sigma(az)$.

On developing the right-hand side of (A.5.23) we obtain

\[
\tilde{K}_w \ast \tilde{K}_{U^\circ w}(u^\circ, x, y) = \int_{z \in A^1} \mathcal{L}_\psi(xz) \otimes \mathcal{L}_\psi(-\frac{1}{2} s^{-1} z^2 + s^{-1} xy - \frac{1}{2} s^{-1} y^2)
\]

\[
\simeq \int_{A^1} \mathcal{L}_\psi(xz - \frac{1}{2} s^{-1} z^2 + s^{-1} xy - \frac{1}{2} s^{-1} y^2)
\]

\[
\simeq \int_{A^1} \mathcal{L}_\psi(-\frac{1}{2} s^{-1} (z - sx - y)^2) \otimes \mathcal{L}_\psi(\frac{1}{2} sx^2 + xy)
\]

\[
\simeq \int_{A^1} \mathcal{L}_\psi(-\frac{1}{2} s^{-1} z^2) \otimes \mathcal{L}_\psi(\frac{1}{2} sx^2 + xy).
\]

By applying change of coordinates $z \mapsto sz$ under the last integration we obtain

\[(A.5.24) \quad \int_{A^1} \mathcal{L}_\psi(-\frac{1}{2} s^{-1} z^2) \otimes \mathcal{L}_\psi(\frac{1}{2} sx^2 + xy) \simeq \int_{z \in A^1} \mathcal{L}_\psi(-\frac{1}{2} s^2) \otimes \mathcal{L}_\psi(\frac{1}{2} sx^2 + xy).
\]

Now,

\[(A.5.25) \quad A_w \otimes A_{U^\circ w}(u^\circ) = G(\psi, \sigma)[2](1) \otimes G(\psi, \sigma)[2](1).
\]
Combining (A.5.24) and (A.5.25) we obtain that the right-hand side of (A.5.23) is isomorphic to
\[
\left( G(\psi_s, \sigma)[2](1) \otimes \int_{\mathbb{A}^1} \mathcal{L}\psi(-\frac{1}{2} sz^2) \right) \otimes \left( G(\psi, \sigma)[2](1) \otimes \mathcal{L}\psi(\frac{1}{2} sz^2 + xy) \right).
\]
The main argument is the existence of the following isomorphism:
\[
G(\psi_s, \sigma)[2](1) \otimes \int_{\mathbb{A}^1} \mathcal{L}\psi(-\frac{1}{2} sz^2) \simeq \prod_{\ell},
\]
which is a direct consequence of the following lemma:

**Lemma A.13 (Main lemma).** There exists a canonical isomorphism of sheaves on \( G_{\mathbb{m}} \)
\[
\int_{\mathbb{A}^1} \mathcal{L}\psi(z) \otimes \mathcal{L}\sigma(z) \simeq \int_{\mathbb{A}^1} \mathcal{L}\psi(z^2),
\]
where \( s \in \mathbb{G}_{\mathbb{m}} \).

**Proof.** The parameter \( s \) does not play any essential role in the argument. Therefore, it is sufficient to prove

(A.5.26) \[
\int_{\mathbb{A}^1} \mathcal{L}\psi(z) \otimes \mathcal{L}\sigma(z) \simeq \int_{\mathbb{A}^1} \mathcal{L}\psi(z^2).
\]
Define the morphism \( p : \mathbb{G}_{\mathbb{m}} \to \mathbb{G}_{\mathbb{m}} \), \( p(x) = x^2 \). The morphism \( p \) is an étale double cover. We have \( p_* \prod_{\ell} \simeq \mathcal{L}\sigma \oplus \prod_{\ell} \). Now on developing the left-hand side of (A.5.26) we obtain
\[
\int_{\mathbb{A}^1} \mathcal{L}\psi(z) \otimes \mathcal{L}\sigma(z) = \pi_!(\mathcal{L}\psi \otimes \mathcal{L}\sigma) \simeq \pi_!(\mathcal{L}\psi \otimes (\mathcal{L}\sigma \oplus \prod_{\ell})).
\]
The first step is just a translation to conventional notation, where \( \pi \) stands for the projection \( \pi : \mathbb{G}_{\mathbb{m}} \to \text{pt} \). The second isomorphism uses the fact that \( \pi_* \mathcal{L}\psi \simeq 0 \). Next,
\[
\pi_!(\mathcal{L}\psi \otimes (\mathcal{L}\sigma \oplus \prod_{\ell})) \simeq \pi_!(\mathcal{L}\psi \otimes p_* \prod_{\ell}) \simeq \pi_! p^* \mathcal{L}\psi = \int_{\mathbb{A}^1} \mathcal{L}\psi(z^2). \quad \Box
\]

This completes the proof of proposition A.11. \quad \Box

**Appendix B. Proofs section**

We fix the following notation. Let \( h = \frac{1}{p} \), where \( p \) is a fixed prime \( \neq 2, 3 \). Consider the lattice \( \Lambda^* \) of characters of the torus \( \mathbb{T} \) and the quotient vector space \( V = \Lambda^*/p\Lambda^* \). The integral symplectic form on \( \Lambda^* \) is specialized to give a symplectic form on \( V \), i.e., \( \omega : V \times V \to \mathbb{F}_p \). Fix \( \psi : \mathbb{F}_p \to \mathbb{C}^* \) as the additive character \( \psi(t) = e^{2\pi i t h} \), and let \( \mathcal{A}_h \) be “the algebra of functions on the quantum torus” and \( \Gamma \simeq \text{SL}_2(\mathbb{Z}) \) its group of symmetries.
B.1. Proof of Theorem 2.3. Basic set-up: Let \((\pi_\hbar, \mathcal{H}_\hbar)\) be a representation of \(A_\hbar\), which is a representative of the unique irreducible class which is fixed by \(\Gamma\) (cf. Theorem 2.2). Let \(\rho_\hbar: \Gamma \rightarrow \text{PGL}(\mathcal{H}_\hbar)\) be the associated projective representation. Here we give a proof that \(\rho_\hbar\) can be linearized in a unique way which factors through the quotient group \(\Gamma_p \simeq \text{SL}_2(\mathbb{F}_p)\).

\[
\begin{array}{c}
\Gamma \\
\downarrow_{\rho_\hbar} \downarrow_{\bar{\rho}_\hbar} \\
\text{GL}(\mathcal{H}_\hbar)
\end{array}
\]

The proof will be given in several steps.

**Step 1. Uniqueness.** The uniqueness of the linearization follows directly from the fact that the group \(\text{SL}_2(\mathbb{F}_p)\), \(p \neq 2, 3\), has no characters.

**Step 2. Existence.\(^{16}\)** The main technical tool in the proof of existence is a construction of a finite-dimensional quotient of the algebra \(A_\hbar\). Let \(A_p\) be the unital associative algebra generated over \(\mathbb{C}\) by the symbols \(\{s(v) \mid v \in V\}\) and the relations

\[
s(u)s(v) = \psi\left(\frac{1}{2} \omega(u, v)\right)s(u + v), \quad s(0) = 1.
\]

The algebra \(A_p\) is nontrivial and the vector space \(V\) gives on it a standard basis. In fact, \(A_p\) is isomorphic to a quotient \(\mathbb{C}[H] \otimes \mathbb{C}[Z]\) of the group algebra of \(H\), where \(H\) is the Heisenberg group defined in A.1.2, \(Z\) its center, and the tensor product is formed using the homomorphism \(\mathbb{C}[Z] \rightarrow \mathbb{C}\) defined by \(\psi\). We have the following map:

\[
s : V \rightarrow A_p, \quad v \mapsto s(v).
\]

The group \(\Gamma_p\) acts on \(A_p\) by automorphisms through its action on \(V\). The epimorphism \(\Lambda^* \rightarrow V\) induces a homomorphism of algebras

\[
q : A_\hbar \rightarrow A_p.
\]

The homomorphism (B.1.2) respects the actions of the group of symmetries \(\Gamma\) and \(\Gamma_p\) respectively. This is summarized in the following commutative diagram:

\[
\begin{array}{ccc}
\Gamma \times A_\hbar & \longrightarrow & A_\hbar \\
(p, q) \downarrow & & \downarrow q \\
\Gamma_p \times A_p & \longrightarrow & A_p
\end{array}
\]

where \(p : \Gamma \rightarrow \Gamma_p\) is the canonical quotient map.

\(^{16}\)This statement and its proof work more generally for all Planck constants of the form \(\hbar = M/N\), with \(M, N\) co-prime integers, and \(N\) odd. One should replace then the finite Field \(\mathbb{F}_p\) with the finite ring \(\mathbb{Z}/N\mathbb{Z}\).
Step 3. Next, we construct an explicit representation of $A_p$:

$$\pi_p : A_p \longrightarrow \text{End}(H).$$

Let $V = V_1 \oplus V_2$ be a Lagrangian decomposition of $V$. In our case $V$ is two-dimensional, therefore $V_1$ and $V_2$ are linearly independent lines in $V$. Take $H = S(V_1)$ to be the vector space of complex valued functions on $V_1$. For an element $v \in V$ define

$$(B.1.4) \quad \pi_p(v) = \psi(-\frac{1}{2} \omega(v_1, v_2))L_{v_1}M_{v_2},$$

where $v = v_1 + v_2$ is a direct decomposition $v_1 \in V_1, v_2 \in V_2$, $L_{v_1}$ is the translation operator defined by $v_1$

$$L_{v_1}(f)(x) = f(x + v_1), \quad f \in S(V_1)$$

and $M_{v_2}$ is a notation for the operator of multiplication by the function $M_{v_2}(x) = \psi(\omega(x, v_2))$. One checks that the formulas given in (B.1.4) satisfy the relations (B.1.1) and thus constitute a representation of the algebra $A_p$, and this representation corresponds to the induced representation $\text{Ind}^H_{V_2} \mathbb{C}\psi$ of $H$ considered in A.1.3.

As a consequence of constructing $\pi_p$ we automatically proved that $A_p$ is nontrivial. It is well known that all linear operators on $S(V_1)$ are linear combinations of translation operators and multiplication by characters. Therefore, $\pi_p : A_p \longrightarrow \text{End}(H)$ is surjective. As $\dim(A_p) \leq p^2$, $\pi_p$ is a bijection. This means that $A_p$ is isomorphic to a matrix algebra $A_p \simeq M_p(\mathbb{C})$.

Step 4. Completing the proof of existence. The group $\Gamma_p$ acts on $A_p$. Therefore, it acts on the category of its representations. However, $A_p$ is isomorphic to a matrix algebra; therefore it has unique irreducible representation, up to isomorphism. This is the standard representation of dimension $p$. But $\dim(H) = p$, therefore $\pi_p$ is an irreducible representation and its isomorphism class is fixed by $\Gamma_p$ so that we have a pair

$$\pi_p : A_p \longrightarrow \text{End}(H),$$
$$\rho_p : \Gamma_p \longrightarrow \text{PGL}(H)$$

satisfying the Egorov identity

$$\rho_p(B)\pi_p(v)\rho_p(B^{-1}) = \pi_p(Bv),$$

where $B \in \Gamma_p$ and $v \in A_p$.

It is a well known general fact (attributed to I. Schur) that the group $\Gamma_p$, where $p$ is an odd prime, has no nontrivial projective representations. This
means that $\rho_p$ can be linearized\textsuperscript{17} to give

$$\rho_p : \Gamma_p \longrightarrow \text{GL}(\mathcal{H}).$$

Now take

$$\mathcal{H}_h = \mathcal{H}, \quad \pi_h = \pi_p \circ q, \quad \rho_h = \rho_p \circ p.$$ 

Because $q$ intertwines the actions of $\Gamma$ and $\Gamma_p$ (cf. diagram (B.1.3)) we see that $\pi_h$ and $\rho_h$ are compatible; namely, the Egorov identity is satisfied

$$\rho_h(B)\pi_h(f)\rho_h(B^{-1}) = \pi_h(fB),$$

where $B \in \Gamma_p$ and $f \in \mathcal{A}_h$. Here the notation $\pi_h(fB)$ means to apply any pre-image $\overline{B} \in \Gamma$ of $B \in \Gamma_p$ on $f$. In particular, this implies that the isomorphism class of $\pi_h$ is fixed by $\Gamma$. Since such a representation $\pi_h$ is unique up to an isomorphism, (Theorem 2.2), our desired object has been obtained. \hfill \Box

B.2. Proof of Lemma 4.3. Basic set-up: Let $(\pi_h, \mathcal{H}_h)$ be a representation of $\mathcal{A}_h$, which is a representative of the unique irreducible class which is fixed by $\Gamma$ (cf. Theorem 2.2). Let $\rho_h : \Gamma_p \longrightarrow \text{GL}(\mathcal{H}_h)$ be the associated honest representation of the quotient group $\Gamma_p$ (see Theorem 2.3 and Proof B.1). Recall the notation $Y_0 = \Gamma_p \times \Lambda^*$. We consider the function $F : Y_0 \longrightarrow \mathbb{C}$ defined by the following formula:

$$(B.2.1) \quad F(B, \xi) = \text{Tr}(\rho_h(B)\pi_h(\xi)),$$

where $\xi \in \Lambda^*$ and $B \in \Gamma_p$. We want to show that $F$ factors through the quotient set $Y = \Gamma_p \times \Lambda^*$.

![Diagram](image.png)

The proof is immediate, when we take into account the construction given in Section B.1. Let $\pi_p$ be the unique (up to isomorphism) representation of the quotient algebra $\mathcal{A}_p$. As was stated in B.1, $\pi_h$ is isomorphic to $\pi_p \circ q$, where $q : \mathcal{A}_h \longrightarrow \mathcal{A}_p$ is the quotient homomorphism between the algebras. This means that $\pi_h(\xi) = \pi_p(q(\xi))$ depends only on the image $q(\xi) \in \Lambda$, and formula (B.2.1) solves the problem. \hfill \Box

B.3. Proof of Theorem 4.4. Basic set-up: In this section we use the notation of Section B.1 and Appendix A. Set $Y = \text{Sp} \times \Lambda$ and let $\alpha : \text{Sp} \times Y \longrightarrow Y$ denote the associated action map. Let $F : Y \longrightarrow \mathbb{C}$ be the function appearing in the statement of Theorem 4.4, i.e., $F(B, v) = \text{Tr}(\rho_p(B)\pi_p(v))$, where $B \in \text{Sp}$

\textsuperscript{17}See Appendix A for an independent proof based on "The method of canonical Hilbert space".
and \( v \in V \). We use the notation \( V, \Sp \) and \( Y \) to denote the corresponding algebraic varieties. We construct a Weil object \( F \in \mathcal{D}^b_c(Y) \) having the properties 1–4 stated in Theorem 4.4.

Construction of the sheaf \( F \). We use the notation of Appendix A. Let \( H \) be the Heisenberg group. As a set we have \( H = V \times \mathbb{F}_q \). The group structure is given by the multiplication rule \((v, \lambda) \cdot (v', \lambda') = (v + v', \lambda + \lambda' + \frac{1}{2} \omega(v, v'))\). We fix a section \( s : V \rightarrow H, s(v) = (v, 0) \). The group \( \Sp \) acts by automorphisms on the group \( H \), through its tautological action on the vector space \( V \); i.e., \( g \cdot (v, \lambda) = (gv, \lambda) \). We define the semi-direct product \( G = \Sp \rtimes H \) and consider the map \((\text{Id}, s) : Y \rightarrow G\). We use the notation \( H \) and \( G \) to denote the corresponding algebraic varieties.

Let \( K \) be the Weil representation sheaf (see Theorem A.5). Define

\[
F = \text{Tr}(K|_Y),
\]

where \( \text{Tr} \) is defined in analogy to the operation of taking trace in the set-theoretic framework; that is, we take

\[
F(g, v) = \int_{x \in \mathbb{A}^1} K(g, v, x, x),
\]

where we use the notation \( \int_{x \in \mathbb{A}^1} \) to denote integration with compact support along the \( x \)-variable. We prove that the sheaf \( F \) satisfies Properties 1–4.

Proof of Property 2. Property 2 follows easily. One should observe that the collection of operators \( \{\pi_p(v)\}_{v \in V} \) extends to a representation of the group \( H \), which we will also denote by \( \pi_p \). The representations \( \rho_p \) and \( \pi_p \) glue to a single representation \( \rho_p \rtimes \pi_p \) of the semi-direct product \( G \). It is a direct verification, that the representation \( \rho_p \rtimes \pi_p \) is isomorphic to the representation \( \rho \rtimes \pi \) constructed in Appendix A. Hence, we can write

\[
fF = f^{\text{Tr}(K|_Y)} = \text{Tr}(f^K|_Y) = \text{Tr}(K|_Y) = F.
\]

In the above equation we use the fact that the operation of taking the geometric trace commutes with sheaf-to-function correspondence. This proves Property 2.

Proof of Property 3. This principally follows from the multiplication property of the sheaf \( K \) (Theorem A.5, Property 2). More precisely, using the multiplication property we obtain the following isomorphism:

\[
\mathcal{K}_{|_S} * \mathcal{K} * \mathcal{K}_{|_{S^{-1}}} \simeq L^*_S R^*_S \mathcal{K},
\]

where \( L_S, R_{S^{-1}} \) denotes left multiplication by \( S \) and right multiplication by \( S^{-1} \) on the group \( G \), respectively. Next,

\[
\alpha_S^* F \simeq \text{Tr}(\alpha_S^* K|_Y) \simeq \text{Tr}(L^*_S R^*_S \mathcal{K}|_Y) \simeq \text{Tr}(\mathcal{K}_{|_S} * \mathcal{K}|_Y * \mathcal{K}_{|_{S^{-1}}}).
\]
Finally, we have the following isomorphisms

$$\text{Tr}(K|_S \ast K|_Y \ast K|_{S-1}) \simeq \text{Tr}(K|_{S-1} \ast K|_S \ast K|_Y)$$

and

$$K|_{S-1} \ast K|_S \simeq \mathcal{I},$$

where the first isomorphism is the basic property of the trace. Its proof in the geometric setting is a result of direct diagram chasing. Structurally, it follows the same lines as in the usual set-theoretic setting. The second isomorphism is a consequence of the multiplication property of $K$. This completes the proof of Property 3.

**Proof of Property 4.** This property is directly verified using Corollary A.12 and the formulas (A.5.12), (A.5.11) for $K_B$ and $K_\pi$ respectively.

**Proof of Property 1.** We will use the notation $K_\rho$ and $K_\pi$ to denote the restriction of the sheaf $K$ to the subgroups $\text{Sp}$ and $\text{H}$ respectively. We recall the formula $K_\pi(h, x, y) = \mathcal{L}_\psi(\frac{1}{2}pq + px + \lambda) \otimes \delta_{y=x+q}$, where $h = (q, p, \lambda)$. Moreover, it is easy to verify that the sheaf $K_\rho$ is an irreducible $[\dim(\text{Sp}) + 1]$-perverse Weil sheaf of pure weight zero. Finally, we have that

$$(B.3.1) K \simeq K_\rho \ast K_\pi.$$

Let $h = (q, p, 0)$. Now write

$$\mathcal{F}(g, h) \simeq \text{Tr}(K(g, h))$$

$$\simeq \int_{x \in \mathbb{A}^1} K_\rho(g, x, x - q) \otimes \mathcal{L}_\psi(-\frac{pq}{2} + px)$$

$$\simeq \int_{x \in \mathbb{A}^1} K_\rho(g, \frac{x + q}{2}, \frac{x - q}{2}) \otimes \mathcal{L}_\psi(\frac{1}{2}px).$$

The second isomorphism is a direct consequence of the formulas of the sheaves involved and isomorphism (B.3.1). The third isomorphism is a change of variables $(q, 2x - q) \rightarrow (q, x)$. Consider the isomorphism $\beta : \text{Sp} \times \mathbb{A}^1 \times \mathbb{A}^1 \rightarrow \text{Sp} \times \mathbb{A}^1 \times \mathbb{A}^1$, defined by $\beta(g, q, x) = (g, \frac{x+q}{2}, \frac{x-q}{2})$. The last term in the chain of isomorphisms above is equivalent to taking (nonnormalized) fiber-wise Fourier transform of $\beta^*K_\rho$ considered as a sheaf on the line bundle $(\text{Sp} \times \mathbb{A}^1) \times \mathbb{A}^1 \rightarrow (\text{Sp} \times \mathbb{A}^1).$ This implies using the theory of the $\ell$-adic Fourier transform (cf. [20]) that $\mathcal{F}$ is geometrically irreducible $[\dim(\text{Y})]$- perverse of pure weight zero. This concludes the proof of Property 1, and of Theorem 4.4. □

**B.4. Computations for the Vanishing Lemma (Lemma 4.6).** In the computations we use some finer technical tools from the theory of $\ell$-adic cohomology. The interested reader can find a systematic study of this material in [19], [22], [27], [1].
We identify the standard torus $T \subset \text{SL}_2$ with the group $\mathbb{G}_m$. Fix a nontrivial character sheaf\(^{18}\) $\mathcal{L}_\chi$ on $\mathbb{G}_m$. Denote by $\mathcal{L}_\psi$ a nontrivial character sheaf on $\mathbb{G}_a$. Fix $\lambda, \mu \in \mathbb{A}^1$ with $\lambda \cdot \mu \neq 0$. Consider the variety $X = \mathbb{G}_m - \{1\}$, the sheaf
\[ E = \mathcal{L}_\psi(\frac{1}{2} a + 1 - \lambda \cdot \mu) \otimes \mathcal{L}_\chi, \]
(B.4.1)

on $X$ and the canonical projection $\text{pr} : X \to \text{pt}$. Note that $E$ is a nontrivial one-dimensional local system on $X$. The proof of the lemma will be given in several steps

Step 1. Vanishing. We want to show that $H^i(\text{pr}_! E) = 0$ for $i = 0, 2$. By definition
\[ H^0(\text{pr}_! E) = \Gamma(Y, j_! E), \]
where $j : X \hookrightarrow Y$ is the imbedding of $X$ into a compact curve $Y$. The statement follows since
\[ \Gamma(Y, j_! E) = \text{Hom}(\mathcal{O}_\ell, j_! E). \]
It is easy to see that any nontrivial morphism $\mathcal{O}_\ell \to j_! E$ should be an isomorphism on $X$; hence $\text{Hom}(\mathcal{O}_\ell, j_! E) = 0$.

For the second cohomology we have
\[ H^2(\text{pr}_! E) = H^{-2}(D \text{pr}_! E)^* = H^{-2}(\text{pr}_* D E)^* = \Gamma(X, D E[-2])^*, \]
where $D$ denotes the Verdier duality functor\(^{19}\) and $[-2]$ is the translation functor. The first equality follows from the definition of $D$, the second equality is the Poincaré duality and the third equality easily follows from the definitions. Again, since the sheaf $D E[-2]$ is a nontrivial one-dimensional local system on $X$ we have
\[ \Gamma(X, D E[-2]) = \text{Hom}(\mathcal{O}_\ell, D E[-2]) = 0. \]

Step 2. Dimension. We claim that $\dim H^1(\text{pr}_! E) = 2$. The (topological) Euler characteristic $\chi(\text{pr}_! E)$ of the sheaf $\text{pr}_! E$ is the integer defined by the formula
\[ \chi(\text{pr}_! E) = \sum_i (-1)^i \dim H^i(\text{pr}_! E). \]
Hence, from the vanishing of cohomologies (Step 1) we deduce

\(^{18}\)That is, a one-dimensional local system on $\mathbb{G}_m$ that satisfies the property $m^* \mathcal{L}_\chi \simeq \mathcal{L}_\chi \boxtimes \mathcal{L}_\chi$, where $m : \mathbb{G}_m \times \mathbb{G}_m \to \mathbb{G}_m$ is the multiplication morphism.

\(^{19}\)In the vector bundle interpretation, one might think of $D$ as the operation of taking the dual vector bundle with the dual connection.
Substep 2.1. It is sufficient to show that $\chi(\text{pr}_! \mathcal{E}) = -2$. The actual computation of the Euler characteristic $\chi(\text{pr}_! \mathcal{E})$ is done using the Ogg-Shafarevich-Grothendieck formula (see [7], [27], [19, Chap. 2], and references therein)

$$\text{rk}(\mathcal{E}) \cdot \chi(\text{pr}_! \mathbb{Q}_\ell) - \chi(\text{pr}_! \mathcal{E}) = \sum_{y \in Y - X} \text{Swan}_y(\mathcal{E}).$$  \hspace{1cm} (B.4.2)

Here $\text{rk}(\mathcal{E}) = 1$ is the rank of the sheaf $\mathcal{E}$, $\mathbb{Q}_\ell$ denotes the constant sheaf on $X$, and $Y = \mathbb{P}^1$ is the smooth compactification of $X$. In other words, this formula expresses the difference of $\text{rk}(\mathcal{E}) \cdot \chi(\text{pr}_! \mathbb{Q}_\ell)$ from $\chi(\text{pr}_! \mathcal{E})$ as a sum of local contributions, called Swan conductors. We will not give here the formal definition of the Swan conductor (see [19], [20], [27]), but instead we will formulate some of the properties and known results that are needed for our calculations.

In our case $\chi(\text{pr}_! \mathbb{Q}_\ell) = -1$, and by using formula (B.4.2) we get

Substep 2.2. It is enough to show that $\text{Swan}_0(\mathcal{E}) + \text{Swan}_1(\mathcal{E}) + \text{Swan}_\infty(\mathcal{E}) = 1$. We would like now to understand the effect of the tensor product on the Swan conductor. Choose a point $y \in Y - X$, and let $L_1, L_2 \in D^b_c(\mathcal{X})$ be two sheaves with $L_1$ being lisse (smooth) in a neighborhood of $y$. We have

$$\text{Swan}_y(L_1 \otimes L_2) = \text{rk}(L_1) \cdot \text{Swan}_y(L_2).$$  \hspace{1cm} (B.4.3)

In particular, using property (B.4.3) and the explicit formula (B.4.1) of the sheaf $\mathcal{E}$, we deduce that

$$\text{Swan}_1(\mathcal{E}) = \text{Swan}_\infty(\mathcal{L}_\psi),$$
$$\text{Swan}_\infty(\mathcal{E}) = \text{Swan}_\infty(\mathcal{L}_\chi),$$
$$\text{Swan}_0(\mathcal{E}) = \text{Swan}_0(\mathcal{L}_\chi).$$

Substep 2.3. We have $\text{Swan}_\infty(\mathcal{L}_\psi) = 1$, and $\text{Swan}_\infty(\mathcal{L}_\chi) + \text{Swan}_0(\mathcal{L}_\chi) = 0$. By applying the Ogg-Shafarevich-Grothendieck formula to the Artin-Schreier sheaf $\mathcal{L}_\psi$ on $\mathbb{A}^1$ and the projection $\text{pr}: \mathbb{A}^1 \to \text{pt}$, we find that

$$\text{Swan}_\infty(\mathcal{L}_\psi) = \chi(\text{pr}_! \mathbb{Q}_\ell) - \chi(\text{pr}_! \mathcal{L}_\psi) = 1 - 0 = 1.$$  \hspace{1cm} (B.4.4)

Finally, we apply the formula (B.4.2) to the sheaf $\mathcal{L}_\chi$ on $\mathbb{G}_m$ and the projection $\text{pr}: \mathbb{G}_m \to \text{pt}$ and conclude

$$\text{Swan}_\infty(\mathcal{L}_\chi) + \text{Swan}_0(\mathcal{L}_\chi) = \chi(\text{pr}_! \mathbb{Q}_\ell) - \chi(\text{pr}_! \mathcal{L}_\chi) = 0 - 0 = 0.$$  \hspace{1cm} (B.4.5)

Note that, in (B.4.4) and (B.4.5) we use the fact that $\text{pr}_! \mathcal{L}_\psi$ and $\text{pr}_! \mathcal{L}_\chi$ are the 0-objects in $D^b_c(\text{pt})$.

This completes the computations of the Vanishing Lemma. \hfill \square
